THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

VOLUME XXVIII.

FROM NOVEMBER 6, 1891, TO APRIL 29, 1892.

LONDON:
Printed and Published for the Proprietors by GEORGE TUCKER, at the Offices of "THE ELECTRICIAN," Salisbury-court, Fleet-street, E.C.

1892.

Digitized by Google

INDEX TO "THE ELECTRICIAN."

VOL. XXVIII.

General Alphabetical Index.

A

Aachen, 342
Aberdeen, 420
Académie des Sciences, 269
Accumulator Cars in Rome, 397
Accumulator, D.P., 423
Accumulator Litigation in Belgium, 478
Accumulator Traction in Paris, 510
Accumulators in Telegraphy, 624
Accumulators, On the Construction of a Battery of Miniature: by C. L. Weber, 218
Acids on Aluminium, Action of, 189
ADAMS, ALEX. J. S.
A Buried Microphone, 661
Altenmarkt, 3
Alternate Current Measurement, Principles of: by H. E. Harrison, 170, 196, 223, 245
Alternate Current Motors, 396
Alternate Current Transformer Curves, Harmonic Analysis of: by Dr. J. A. Fleming, 291, 295, 326
Alternate Currents, Some Experimental Investigations of: by Alexander Siemens, 431, 461, 492. *Discussion*, 492, 521
Alternating Current Machines, Some Curves from: by W. B. Lewis, 90
Alternating Currents, Note on the Interference with: by M. H. Kilgour, 201
Alternating Sparking Distances, 201
Alternator, Mather and Platt's, 575
Aluminium, Action of Acids on, 189
Aluminium, Price of, &c., 25, 316, 502
Aluminium Soldering, 450
Amalgamation of the Edison and Thomson-Houston Companies, The Rumoured, 406
American Dynamo Practice, Notes on: by J. D. Dallas, 519
American Institute of Electrical Engineers, 421, 533
American Supply Station, a New, 486
Analogies, Electrical, 214
ANDERSEN, F. V.
Description of Standard Volt and Ampere Meter, 69, 94, 123. *Discussion*, 125
Antwerp, 449
Arc Lamps Automatic Switch for Suspended, 167
Arc Light Carbons, 344
Arc, Notes on the Light of the Electric: by Alex. P. Trotter, 687
Arcs, Normal and Hissing: by J. R. Cravath, 568
Ardois System of Electric Night Signals, 188
Armature Resistance, 410
Arrol Train Approach Indicator, 189
Art Fittings at the Crystal Palace, 411
Artesian Well in the City, 188
Asbestos Porcelain, 189, 562
Association Suisse des Electriciens, 343
Athens, 594
Atmospheric Electricity, 596
Atmospheric Electricity from a Captive Balloon, Observations of, by E. Semmola, 455
Aurora, Artificial, 651
Aurora Borealis, 395
Automatic Machine, An Ingenious Electric, 449
Auxiliary Dynamo Feeder Pressure Regulation, 329
Ayrton (William Edward), Biographical Sketch of, 346
AYRTON, Prof. W. E.
Electric Meters, Motors, and Money Matters, 640
Electrotechnics, 323, 353
Improved Quadrant Electrometer, 659
Note on Rotatory Currents, 178
Thermal Emissivity of Thin Wires in Air, 119

B

BAGARD, HENRI.
A Thermo-Electric Standard of Electromotive Force, 192
Bahamas, A Cable to, 107
Bath Public Arc Lamps, 593
Batteries (Secondary)—
Commelin-Finot Cadmium, 626
D.P., 423
Batteries, Secondary and Chemists, 188
Batteries (Large Current) for Experimental Work, 625
Battery Competition, Primary, 188
Belgian Telephone Service, 262
Belt Formula, 189
Belts (Large) for an Electric Power Station, 3
Benardos Welding Process, 198
Bench and the Bar, Science of the, 562
Benham and Froud's Exhibit at the Crystal Palace, 629
BERESFORD, MAJOR C. F. C.
Telephone at Home and in the Field, 667
Berlin, 189
Berlin-Königsberg Trunk Wire, 161
Berliner Electricitatswerke, 421
Berliner Microphone, 107, 128, 138, 153, 243
Berliner's "Electrodes," 389
Bermondsey, 316
Bilbao, 136
Bismuth, 625
Blackman Fan (Electric), 403
Blackpool, 448
Blackpool Tramway, 55, 83
Blankenburg, 2
Bleaching, Electric, 361
Block Signalling in America, 332
BLONDLOT, R.
Experimental Determination of the Rate of Propagation of Electro-Magnetic Waves, 85
Recent Researches on Electrical Oscillations, 627
Blondlot's Researches on Hertzian Oscillations, 623, 628
Board of Trade and Overhead Wires, 190
Bockenheim, 396
Boilers, On Some Details in the Construction of Modern Lancashire: by Saml. Boswell 43
Boston West End Street Railway, Lower Station of, 3
BOSWELL, SAMUEL
On Some Details in the Construction of Modern Lancashire Boilers, 43
Bourne's (Messrs.) High Voltage Experiments at the Central Institution, 512
Bradford, 160, 371, 373, 398, 624
Bremen, 421
Breslau Central Station, 533
Brett, Mr. Jacob, A Forgotten Telegraph Pioneer, 64
BREW, WM.
Note on the use of an Electro-Dynamometer, 600
Brighton, 25, 57, 84, 107, 190
Brighton and Hove Electric Lighting Company, 397
Bristol, 215, 342, 533
Brooklyn, Trolley System in, 260
Brush Company's Exhibit at the Crystal Palace, 628
Brussells Municipal Electric Lighting Contract, 675
Buffalo Arc Light Stations, 422
Bulgaria, Interurban Telephony in, 317
Buoys in New York Harbour, Electric Lighting of, 663
Burnley, 342

C

Cable Communication in the Indian Ocean, 56
Cable Communication with Spain, 107
Cable Extensions, 82, 372, 422, 533
Cable Interruptions and Repairs, 136, 137, 160, 244, 345, 449, 478, 563
Cable in the Pacific, Surveying for a Submarine, 108
Cable, Method of Picking up a, 516
Cable Service, Brazilian Government and, 107
Cable, Sub-Lacustrine, 625
Cable Transformer, Siemens, 86
Cables, Electric Light, 62
Cables, Insulation of, 172
Cadogan Electric Light Company, 107
Calcutta, 188
Calico Printing, Electricity in, 160
Cambridge, 214, 420, 533
Canadian Telegraphs, 532
Candle Power of Incandescent Lamps as related to Current, Voltage and Energy Consumed, by L. A. Ferguson and D. A. Center, 112
Cannstadt, 508
CARDEW, MAJOR P.
On a Differential Electrostatic Method of Measuring High Electrical Resistances, 430
Cardew's Method of Measuring Insulation Resistance, 419
Cardiff, 160
"CARLETON."
Economic Limit of Large Power Units, 150
Caustic Soda and Chlorine Electrolytic Process, 255
CENTER, DAVID A.
On the Candle Power of Incandescent Lamps as related to Current, Voltage and Energy consumed, 112
Central Lighting Stations, List of, 232
Central London Railway, 82, 188
Central Station Revenue in Paris, 3
Ceylon, Electric Transmission of Power in, 563
Chambers of Commerce, Association of, 484
Chatham, Fatal Electrical Shock at, 480, 532
Chelsea, Competing Companies in, 24, 188
Chelsea Electricity Supply Company, 270
Chemistry, Institute of, 508, 509
Chicago Exhibition, 3, 83, 108, 138, 204, 316, 374, 520, 564
Contract for the Arc Lighting, 593, 623
Electric Launches, 625
Electrical Committee, 398
Exhibition Executive and Royal Commission, 115
Incandescent Lighting, 651, 674
Manchester and the Exhibition, 651
Mansion House Meeting, 508, 520
Power Generators, 626
Proposed International Electrical Congress, 187, 204, 420, 423 478
Choking Coils, by Prof. J. Perry, 531, 545
Christiania-Bergen Trunk Line, 500
Christiania Central Station, 83
Christiania Electric Lighting Tenders, 361
Church Lighting, 268
Church Services by Telephone, 372
City and Guilds of London Institute, 161, 188, 675
City and South London Railway, Proposed Extension of, 82, 215, 317, 437
City, Electric Lighting of the, 57, 127, 136, 480
City of London Electric Lighting Company, 55, 179, 294
Civil Engineers, Benevolent Fund of Institution of, 563
Classes of Electrical Phenomena, 650
Coast Communication, 23, 84, 159, 190, 216, 271, 316, 379, 388, 563, 595, 624, 673, 692
Coast Communication and the Chamber of Shipping, 388
Coast Communication, Parliament and, 692
Coast Lights, 397, 479
Coast Protection, Prof. Tyndall's article on, 624
Coke for Coal at Central Stations, Substitution of, 532
COLLEY, M.
Theory of the Ruhmkorff Coil, 202
Cologne and Dusseldorf Municipal Central Lighting Stations, 35
Cologne Municipal Station, Engines and Dynamos at, 24, 421
Columbian Exhibition, Another, 293
Combinations of Resistances, Major P. A. MacMahon, 601
Combined Resistance of Conductors in Parallel, 166, 235

COMPANIES' MEETINGS, REPORTS, DIVIDENDS, STATUTORY RETURNS, &c.

(Abbreviations:—Mtg., Meetings of Shareholders; Rpt., Reports of Directors; Div., Dividend; Rev., Revenue; Stat., Statutory Returns.)

Actien-Gesellschaft Mix und Genest—475
African Direct Telegraph Company—211
Andrews and Preece—Stat., 505
Anglo-American Telegraph Company—313, 685; Mtg., 364; Stat., 529; Div., 591
Anglo-Canadian Asbestos—Div., 559
Anglo-Roman Gas Company—Mtg., 671
Automatic Electrical Corporation—Stat., 393
Automatic Standard Screw Company—239
Babcock and Wilcox—Div., 417
Barnet and District Electric Supply Co.—Stat., 393
Bell's Asbestos Company—Div., 417
Bell Telephone Company—671
Bengal Telephone Company—Rpt., 621
Bernstein Electric Lamp Company—Stat., 591
Bicester Electricity Supply Co.—157; Stat., 621
Birmingham Electric Supply Co.—Rpt., 416; Mtg., 443
Birmingham House-to-House Electricity Company—Stat., 671
Birmingham Telegraph Factory—239
Bishop's Stortford Electric Light and Steam Laundry Company—Stat., 591
Blackpool Electric Tramway Company—Rpt., 78; Mtg., 182; Stat., 210
Boy Messengers' and Electric Call Co.—Mtg., 475
Brazilian Submarine Telegraph Company—211, 621, 647; Div., 133, 505; Rpt., 696
Brighton and Hove Electric Light Co.—185, 671
British Elec. Installation Contractors—53; Stat., 529
British Electric Light Co.—2; Mtg., 288; Stat., 393
British Electro-Chem. Agency—Mtg., 183; Stat., 289
British Insulated Wire Co.—Mtg., 416; Stat., 505
British Tanning Company—Mtg., 208; Stat., 369
Brompton Electric Fittings Company—Stat., 529
Brush Electrical Engineering Company—53, 333, 393, 445, 529, 559; Div., 313
California Gas, Water, and Electric Lighting Company Syndicate—529
Calls due—591, 647
Camberwell and Islington Electric Light and Power Supply Company—Stat., 339
Cambridge University and Town Electric Lighting Company—
Carbon Electric Company—505; Mtg., 647
Central Electrical Company—289
Central London Railway Company—Mtg., 368
Chatham, Rochester, and District Electric Lighting Company—Stat., 289
Chelsea Electricity supply Co.—210; Stat., 265
Chili Telephone Company—157
Chloride Electrical Storage Syndicate—529
City and South London Railway—Rpt., 328; Mtg., 386; Rev., 21, 53, 103, 133, 167, 185, 212, 240, 260, 289, 313, 339, 369, 393, 417, 445, 475, 530, 559, 591, 621, 647, 671, 697
City and Waterloo Railway Company—393
City of Bath Electric Lighting and Engineering Company—Mtg., 473; Stat., 591
City of London Electric Lighting Company—103, 313; Mtg., 82; Stat., 79
City of Waterford Electric Supply Company—79
City of Westminster Electrical Syndicate—Stat., 591
Clegg's Metal Incandescent Lamp Company of France—393
Column Printing Telegraph Company—393
Commercial Cable Company—595; Div., 157; Rpt., 559
Corlett Electrical Engineering Company—671
County of London Electric Lighting Company—Stat., 184
Crompton and Co.—Mtg., 20, 133; Div., 185
Crompton Electric Supply Company of Australia—Stat., 183
Croydon Tramways Company—Mtg., 444
Crystal Palace District Electric Supply Company—289
Cuba Submarine Telegraph Company—Rev., 21, 133, 157, 265, 369, 475, 621; Div., 333; Stat., 505; Rpt., 368; Mtg., 391
Devon and Cornwall Electricity Supply Co.—529
Devonshire Electric Light and Power Supply Company—Stat., 339
Direct Spanish Telegraph Company—Rev., 21, 157, 369, 505, 621; Rpt., 528; Mtg., 555; Stat., 671
Direct United States Cable Company—Rpt., 264; Mtg., 312; Rev., 265; Stat., 417; Div., 445, 647

COMPANIES' MEETINGS, &c. (*continued*)—

District Messenger Service and News Co.—Stat., 444
Dividends due—591, 672
Durand Electric, Petroleum and Gas Engine and Manufacturing Company—Stat., 475
Eastbourne Electric Light Company—Stat., 558
East Coast Electric Light and Power Supply—Stat., 339
East London Electric Supply Company—79
Eastern Telegraph Company—340, 505, 648; Rev., 21, 266, 369, 475, 621; Div., 133; Mtg., 287, 310; Stat., 444
Eastern Extension, Australasia, and China Telegraph Company—314, 621; Rev., 21, 133, 266, 369, 475, 621; Div., 186; Rpt., 264, 670
Eastern and South African Telegraph Company—53, 103, 186, 340
"Eclipse" Electric Lighting Syndicate—Stat., 265
Edinburgh Electric Supply Corporation—Mtg., 288
Edison and Swan United Electric Light Co.—475
Electric and General Investment Company—648
Electric Construction Corporation—21, 186, 212, 266, 394, 475, 622; Rpt., 184; Mtg., 206, 471, 556, 620; Stat., 369
Electric Date and Time Stamp Company—Stat., 183
Electric Installation and Maintenance Company—Mtg., 133, 239
Electric Lighting Company—185
Electric Meter Company—Stat., 393
Electric Tramcar Syndicate—Stat., 505
Electric Tramways Construction and Maintenance Company—Stat., 475
Electric Trust—21
Electric Welding Company—21, 157; Stat., 313
Electric Wiring and Fittings Company—Stat., 647
Electrical Accessories Company—Stat., 591
Electrical Advertising Syndicate—Stat., 31
Electrical Assets Purchase Company 79 Stat., 185
Electrical Finance Corporation—185
Electrical Fittings Hiring and Maintenance Company—289, 314
Electrical Inventions Company—133; Stat., 103
Electrical Purification Association - Stat., 265
"Electricity and Electrical Engineering" Newspaper Company—417
Electricity Supply Corporation—Mtg., 289
Electro-Chemical Syndicate—559
Electrolytic Caustic Soda and Chlorine Trust—Stat., 417
Elieson Electric Company—559
Elmore's Patent Copper Depositing Company—Rpt., 209; Mtg., 237, 471; Stat., 339
Elmore's Foreign and Colonial Patent Copper Depositing Company—Stat, 647
Elmore's French Patent Copper Depositing Company—475; Mtg., 695
Elmore's American and Canadian Patent Copper Depositing Company—369
Elmore's Wire Manufacturing Company—Rpt., 210, Mtg., 238; Stat., 339
"Energy" Gas Electric Lighting and Power Company—185
Epstein Electric Accumulator Company—185
"Eston" Arc Lamp Syndicate, 505
European Sims-Edison Electrical Torpedo Company—133, 186, 530
Evered and Company—Div., 591
Exeter Electric Lighting Company—22
Exploration Company—Mtg., 444
Fareham Electric Light Co.—Mtg., 591; Stat., 647
Ferranti, S. Z. de—Stat., 417
Field's "M.P." Development Association—Stat., 417
Finsbury Park Electrical Railway—103
Foreign Electric Date and Time Stamp Co. 417
Foreign Pilsen Electric Light and Power Company—Stat., 647
Fowler, Lancaster and Co.—Stat., 339
Fowler-Waring Cables Company—Rpt., 183; Mtg., 208; Stat., 369
Freedman Battery Company—Stat., 417
Gatti's Electric Lighting Station—621
General Electric Company—Stat., 157
General Electric Power and Traction Company—207; Stat., 289
Giant's Causeway, Portrush, and Bush Valley Railway and Tramway Company—Mtg. 392
Globe Electric Company—133; Stat., 211
Globe Telegraph and Trust Company—Div., 289, 621
Gordon Electric Traction Company—Stat., 53, 211
Gordon (J. E. H.) and Co.—Mtg., 338; Stat. 445
Great Northern Telegraph Company—672; Rev., 22, 157, 266, 394, 505, 621
Gülcher (New) Electric Light and Power Company—417; Rpt., 183, 528; Mtg, 209, 557; Stat., 529
Halifax and Bermudas Cable Company—103, 134, 446; Stat., 696
Hastings and St. Leonard's-on-Sea Electric Light Company—Mtg., 340
Henley's (W. T.) Electric Light and Power Company—Stat., 417; Mtg., 592
Hobart Tramway Company—505
Hornsby (Richard) and Sons—Mtg., 158; Stat., 393
House-to-House Electric Light Supply Company—Rpt., 590; Mtg., 619
Humboldt Electric Power and Mining Company—Mtg., 290
India Rubber, Gutta-Percha, and Telegraph Works Company—Rpt., 416; Mtg., 443
Indo-European Telegraph Company—Rpt., 640; Mtg., 694
International Electric Subway Company—185, 559; Mtg., 589
Irish House-to-House Electricity Co.—Stat., 696
Isle of Wight Electric Lighting Company—157; Stat., 265, 647
Islington and General Electric Supply—Mtg., 696
Islington Electric Light Company, 530
Italian Electrical Light and Power Company—Stat., 185
Johannesburg Lighting Company—697
Keighley Electrical Engineering Company—Stat., 265
Kensington and Knightsbridge Electric Lighting Company—Mtg., 503; Stat., 621

COMPANIES' MEETINGS, &c. (*continued*)—

Kensington Court Electric Lighting Co.—Stat., 697
Keswick Electric Light Co.—Rpt., 474; Stat., 591
Keys' Electric Company—Stat., 697
Laing Electric Light and Power Co.—Stat., 697
Lamp Manufacturing Company—Stat., 445
Lancashire and Cheshire House-to-House Electricity Company—Stat., 671
Laurence, Scott and Co.—Stat., 559
Law's Electrical Appliances Co.—21; Stat., 393
Liverpool Electric Supply Company—476; Stat., 239, 671; Mtg., 204
Liverpool Overhead Railway—Mtg, 392
London Electric Supply Corporation—Rpt., 558; Mtg., 587; Stat., 697
Macmahon's Patent Elec. Check System—Stat., 445

Yorkshire House-to-House Electricity Company—Stat., 621

COMPANIES (NEW ELECTRICAL, &c.) REGISTERED—

The following Companies have been Registered under the Limited Liability Acts.

Association for the Protection of Telephone Subscribers, 590
Automatic Gas Lamp Lighter Company, 157
Barrett (R.) and Son, 620
Bicester Electricity Supply Company, 21
Black, Hawthorn, and Co., 590
Boardman's Electric Sun Lamp Patents, 504
California Gas, Water, and Electric Light Company Syndicate, 184
Central Electrical Company, 264
Channel Tubular Railway Preliminary Company, 558
Chelmsford Electric Lighting Company, 620
Chloride Electrical Storage Syndicate, 184
Conelly Motor Company, 132
Corlett Electrical Engineering Company, 647
Cosmo Gear Company, 529
East Coast Engineering Company, 53
Electric Cycle Syndicate, 671
Electric Fittings, Hiring and Maintenance Company, 288
Electric Lighting and General Development Syndicate, 558
Electrical Finance Corporation, 102
Electrical Plant, 474
Electro-Automatic Fire Extinguishing Company, 444
Elmore's American and Canadian Patent Copper Depositing Company, 369
"Eston" Arc Lamp Syndicate, 474
Fire Extinguishing Company of India, 210
Forbes (D. W.) and Co., 157
Globe Electric Company, 53
Hatfield and Co., 444
Hicks, Hargreaves, and Co., 620
Hobart Tramway Company, 504
International Electric Subway Company, 102
Inventions Contract Syndicate, 288
Isle of Wight Electric Lighting Company, 79
Johannesburg Lighting Company, 102
Keighley Electrical Engineering Company, 233
Lightning, 157
Madras Electric Tramways Company, 620
Maybury and Marston, 339
Merryweather and Sons, 558
Metropolitan Light Company, 283
Miller and Co., 132
Mountain's Wire Manufacturing Company, 184
National Telegraph Works Company, 133
New Motor Syndicate, 79
Oakden and Sharpe, 289
Patent Electro-magnetic Syndicate, 133
Pioneer Telephone Company, 474
Pontypool Electric Light and Power Company, 590
Railway Electrical Fog Signal Syndicate, 79
Reading Electric Supply Company, 339
Sectional Standards, 53
Soho Rolling Mills and Metal Works Company, 696
Tavernier's French Patents, 392
Thompson, Ritchie and Co., 475
Wilkes (John), Sons and Mapplebeck, 210

Companies, New, in 1891, 234
Companies Wound-up in 1891, 232
Compound Winding Case, The Brush, 593, 604
Condenser in an Induction Coil, Action of, 187
Condensers for Electric Light and Power Purposes, 372
Condensers in Electric Lighting, Probable Future of, by J. Swinburne, 227, 316
Conductivity of Cast Steel, 345
Conductivity of Water in Contact with Glass, Changes in, 532
Conductors for Electric Lighting and other Purposes, Specification of Insulated, by W. H. Preece, 146, 161, 188 *Discussion*, 461
Conductors, Heating of, by Electric Currents, 136
Conductors, Smythe and Payne's Fireproof System of, 489, 509
Connections for Effecting Several Tests with One Galvanometer, A Plan of, by E. H. Draper, 29
Contact Breaker, Theory of the Automatic, by V. Dvorák, 603
Conventional Electricity, 4
Cooking by Electricity, 477, 508
Copenhagen Central Station, 48, 361
Copper, 343, 478, 532, 595
Copper, on the Apparent Variation of the Electro-Chemical Equivalent of, by M. Vanni, 12
Copper, Weight of, in London Supply Mains, 329
Cork Gas Company and the Electric Light, 397
Cost of Electric Lighting, 242, 531, 534
County Council's Offices, Electric Lighting of, 161
Crane, An Electric Travelling, 684

Digitized by Google

CRAVATH, J. R.
Normal and Hissing Arcs, 568
Crompton (Mr.) at the Electrical Trades Section, 138
Crompton-Howell Accumulator in London Central Stations, 243
Crookes (Prof.) *Fortnightly Review* Article, 341

Crystal Palace Electrical Exhibition—26, 56, 81, 95, 216, 253, 373, 381, 411, 424, 458, 510
Armstrong's Glass Accumulator Cells, 534
Art Fittings, 411
Benham and Froud's Exhibit, 629
Brush Company's Exhibit, 628
Committee of Experts, 594
Crystal Palace District Electric Supply Company, 108
Davey Paxman Boilers, 383
Davey Paxman Engine, 459
Easton and Anderson's Exhibit, 381
Electric Construction Corporation Exhibit, 424
Electric Light Fittings, 383
High Pressure Experiments, 507, 649, 660
Jurors, 510, 562
Kapp Dynamo, 459
Lord Mayor's Visit, 381
MacDonald Conduit, 280
Meeting at the Mansion House, 95
Railway Rates, 293
Rashleigh Phipps and Dawson's Exhibit, 629
Woodhouse and Rawson Exhibit, 424

CUTTRISS, CHARLES.
Telephone Transmitter without Electrodes, 257
Cuttriss Telephone Transmitter, 231

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 703.—Vol. XXVIII. FRIDAY, NOVEMBER 6, 1891. PRICE FOURPENCE. *Annual Subscription (U. K.), 19/6.*

NOTES.

The elaborate system of examination which has hitherto been a prominent feature of the German Patent Office has not only put an end to many attempts to obtain protection, but has effectually prevented the introduction of inventions into that country, since it is not worth while to do business in most cases unless under a patent. The modification of this system, on which Mr. Chapman gives some information in our correspondence columns, seems likely to reduce the annoyance to which inventors have been subjected, and, no doubt, it will in future be worth while to appeal against the decisions which hitherto were practically final. A more important step is the introduction of an altogether new patent system, which appears to be intended to encourage the patenting of small inventions. The process of application is as simple as in this country. No examination is made, no guarantee is given; the duration is only six years, it is true, but our own Patent Office records show how small is the proportion of patents kept up for any longer period. We understand that a model or sample of the invention should be submitted, if possible.

The experiments on electrical discharge which Prof. J. J. Thomson describes in this issue will be found both interesting and instructive. They have been carried out by one of our leading mathematicians, yet no resort is made to symbolic language, and the reasoning adopted will be found clear and straightforward. The work is, therefore, especially valuable, for a research on a subject of this kind is apt to waste itself in a number of pretty but disconnected experiments. Apparently, Prof. Thomson has conclusively proved two important assertions, the truth of which has at times been questioned: namely, that a vacuum is a perfect insulator, and that a piece of iron behaves like a magnetic substance when submitted to magnetising forces alternating with great rapidity. The research is also highly instructive with reference to the probable electrolytic character of all electric discharges through gases. The experiments on the electric glow in gases are in some respects comparable with those made by Mr. Tesla with alternate currents of high frequency. In many ways a glow lamp consisting of a mass of electrically excited gas is an ideal source of light. Its efficiency is many times as great as that of an ordinary glow lamp, while the large amount of luminous surface is also a great point in its favour. Its practical use is, however, problematical, owing to the difficulties attending the production of currents of the requisite frequency, and in transmitting energy by their means with any reasonable efficiency.

One of the minor blessings of the electric light, which, though not so scientific as the absence of carbonic acid, is as distinct an economy as the absence of smoke. We refer to the use of the glow lamp in shop windows, instead of the outside gas lamps, which do so much damage to hats. The first London shops to adopt the electric light were those in Bond-street. To the demands of the Bond-street shopkeepers, in fact, is due the development of the Grosvenor Gallery into a central station; and to them the largest station in the world may be said to owe its existence.

We may naturally turn to the Bond-street windows to learn how the glow lamp may be employed for displaying the best goods in the best manner. In more than one shop we find no shades, and the eye is dazzled by the lamp. In one or two the primitive cone of folded paper is to be found. The lighting of several large windows, containing pictures and statuary, is well managed in a theatrical manner, the lamps being hidden at the sides or above. Next to one of these windows is a shop in which shades are used; but considering the excellent opportunity which is afforded for artistic treatment in such a case, we cannot admire the combination of a china saucer and a coat-hook which is attached to the lamps. The saucer is a shade, the coat-hook is not used to display the wares, but consists of a bit of wire and a brass knob, and acts as a counterpoise to the weight of the saucer. In the next window, where nothing more artistic than portmanteaus are to be seen, some particularly beautiful shades are to be found. They are nothing more than large shells, riveted to a brass support. They are large enough to completely hide the lamp from direct view, but the light shines through the translucent shells, and exhibits their natural colours in a very effective manner.

A letter from Messrs. O. Berend and Co. will be found in the correspondence columns of this issue, in which they challenge the comments made by us last week. They send us also a catalogue containing complete descriptions and many illustrations of Hartmann and Braun's electrical instruments. With reference to our criticism, we notice on p. 5 that the core of the Kohlrausch ammeter has a travel of about four inches. "The scale can be spread out in any desired region by various forms of cores specially worked out." We find that these instruments

Digitized by Google

"are no longer kept in stock for large currents on account of the increased popularity of the alarm clock form of instruments. They are made chiefly for the Recording ampere-meter." But we find a special note to the following effect:—"The scale commences to read at about 10 per cent. of the highest reading." This fully substantiates our criticism; and though the scale can no doubt be spread out in most regions, we should like to see an instrument of this kind in which the first 10 per cent. will be so spread that the whole scale may be uniform. This, we believe, is not possible to produce with a core and a spring, but it might be done with complicated empirically-shaped cams. We therefore still fail to see that this recording instrument can be used for measurements of areas. The illustrations of the straight scales, which will also be found in our correspondence columns, fully confirm our remarks.

We observe that the Hartmann and Braun voltmeters "have a solenoid with a short moving core which, when magnetised, arranges itself in a line with two fixed cores, so as to make a more continuous iron path for the induction. The cores are made of very light soft sheet iron. The movement is opposed by gravity, and the cores are so shaped as to secure large reading near normal pressures." This is an excellent way of making a voltmeter, but surely this is not one of the "new instruments which have not previously been brought before English electricians." We notice in the preface that Messrs. Hartmann and Braun are "always grateful for any suggestions that may occur to the skilled electrician" who uses their instruments. They ought to be particularly grateful to Mr. Evershed for this gravity voltmeter, but perhaps these instruments are not intended for sale in this country. The catalogue from which we have quoted contains a large number of very elaborate scientific apparatus for laboratory work, besides the numerous engine-room instruments, and, for the ground covered, is the most complete instrument catalogue we have seen.

Rumours have reached us that our leading article of last week on motors was about to be demolished, the arguments refuted, and that we should be generally humbled. We have heard that a gas engine costs 5d. an hour, and not 1d., and that three hundred cheap American motors have been sold in London already. Some criticisms would have been very welcome, but none have come to hand. Still more welcome would have been a list of those trades which find it economical to use electric motors on a supply company's service. The advantage of motors for intermittent use is manifest, and was alluded to repeatedly in our article. We ventured to draw the line at present at a four-horse motor running nine hours a day. With intermittent use of a gas engine it is, of course, impossible to maintain a consumption of 25 to 30 cubic feet per horse-power hour; and there will, therefore, be a point at which it becomes possible to use a motor with economy to say nothing of convenience. In determining this point, the greater first cost of a gas engine and its fixing must be taken into account. It is this point which we are anxious to discover, and on which no information has yet been published.

The description of the Van Depoele reciprocating drill by our Frankfort correspondent will be read with interest by those of our readers who have attacked the most difficult problem of constructing an efficient reciprocating motor. The idea of supplying a pulsating current is a great advance upon the use of a commutator forming part of the drill, since sparking is entirely absent and the circuit remains closed. Our correspondent says nothing about the sparking which might reasonably be expected at the commutator of the dynamo. The Thomson-Houston Company are probably equal to the occasion with some such heroic device as an air-blast.

Electric Traction at Brecon.—The Brecon Town Council have decided to take immediate steps for the formation of an electric railway to the Beacons.

Japanese Land Telegraph Lines.—The Japanese land lines, which were interrupted beyond Hiogo and Osaka on Oct. 28th, owing to an earthquake, have now been restored.

Blankenburg.—The whole of the streets of this town were lighted by electricity for the first time on October 19th. The work was carried out by Naglo Brothers, of Berlin.

Litho-Carbon.—A new material, known as litho-carbon, of which enormous deposits have been discovered in Texas, has, says *Industries*, been found to be a most excellent material for insulation.

Electric Light Inspector.—Mr. Arthur Edward Rossiter has been appointed, out of 57 applicants, to act as inspector of electric lighting for the London County Council, at a salary of £200 a year.

Presentation.—Last week the staff of the Bath Central Lighting Station made a presentation to Mr. B. Deakin, who is vacating his post there to take charge of the Brush Company's City station.

Electric Traction in Mexico.—Work has just been commenced on a new railway from Niño Perdido to Coyoacan and the Pedreral Quarries, Mexico, on which it is contemplated to employ electricity.

The Thirtieth Anniversary of the Telephone.—Thirty years ago, on the 26th October, 1861, Philip Reis showed his telephone in public for the first time to the members of the Physical Society of Frankfort.

Stuttgart.—The town of Stuttgart has purchased water power on the river Neckar at Marbach (some 15 miles distant), for £13,500. This power is to be used for running the electric lighting central station being built by the Municipality.

The Preparation of Pure Hydrogen.—Bertholet recommends for the preparation of pure hydrogen the electrolysis of water; then passing the hydrogen so obtained through a solution of permanganate of potash and drying it by means of fused caustic potash.

Electric Launches on the Spree.—Plans have been submitted to the municipal authorities of Berlin for a service of electric launches for passenger traffic on the River Spree. The project is being favourably considered by the Municipal Council.

The Water-Power of Switzerland.—M. Robert Lauterbourg, of Berne, has been studying the subject of the water-power available in Switzerland for electric lighting or electric power transmission. He concludes that 600,000 effective horse-power can be obtained without difficulty.

Tampering with Electric Light Wires.—During the recent "Lohengrin" disturbances in Paris several rioters were lodged for security in the ground floor of the Opera House. There they found something amusing to occupy themselves with. They set themselves to tamper with the electric light wires, which happened to be within their reach, and promptly started a short circuit.

Telephone Litigation in the States.—The American Bell Telephone Company has brought a suit against the Metropolitan Telephone and Telegraph Company of New York, in the United States Circuit Court, to prevent the use or sale of telephones embodying the Bell patents.

The Power Station of the Boston West End Street Railway.—Some twenty pages of the *Electrical Engineer* of New York, of October 21, are devoted to an exhaustive account of the huge power station of the West End Street Railway, of Boston, now approaching completion.

Bristol University College: Engineering Society.—The members of this society made an excursion to Taunton last week, in order to inspect the electric light station and the Electrical Exhibition. The electrical works of the Newton Electrical Company were also visited.

Hammersmith Vestry.—At the last meeting of this vestry the clerk intimated the receipt of a letter from the secretary of the Putney and Hammersmith Electric Light and Power Supply Company, applying for the consent of the Vestry to the application of that Company for a Provisional Order.

Altenmarkt.—According to the *Elektrotechnisches Echo*, a company is in process of formation, with a capital of £50,000, for the purpose of deriving 9,000 H.P. from the rivers Alz and Argen and lighting the neighbouring towns of Traunstein, Trostberg, Burghausen, Simbach Laufen, &c., by electricity.

The Niagara Falls Power Tunnel.—The Niagara Falls power tunnel, which was commenced on October 4, 1890, is making rapid progress. The *Niagara Falls Gazette* says a total of 2,187ft. has been finished out of 6,530ft., and it is estimated that the tunnel to the canal will be completed by the middle of February next.

Large Belts for an Electric Power Station.—It is stated that the two largest driving belts ever made in the United States are now being manufactured in St. Louis for an electric power station. They are of three thicknesses of leather, each 72in. wide and 150ft. long. They weigh about 1,800lb. each, and each belt contains about 200 tanned hides.

A Telephonic Experiment.—On the occasion of a recent bazaar at Bootle a somewhat novel experiment was made in connection with the phonograph and the telephone. The Liverpool exchange was connected to the bazaar, the phonograph installed there being placed in direct communication with the telephone receiver. A song sung at Liverpool was then recorded on the phonograph. This was next successfully transmitted back to Liverpool from the bazaar.

The Cost of Horse Haulage.—In the prospectus just issued by the South-Eastern Metropolitan Tramway Company it is stated that the Company have entered into a contract for 21 years, terminable by the Company by notice after seven years if the Company desire to work the tramway by mechanical power, with the well-known firm of Thomas Tilling, for horsing the cars at a fixed price of 6¼d. per mile, with a minimum daily run per car of 60 miles.

Central Station Revenue in Paris.—The average gross central station receipts per month of the Compagnie Continentale Edison since its inception in August, 1889, have been £5,580. The minimum monthly revenue was that of July, 1890, which amounted to only £3,102; the maximum of £8,448 occurred in February of the present year. The gross receipts for the whole of 1890 amounted to nearly £63,000, and to over £40,000 for the first six months of the present year.

A New Electrical Machine.—At a recent lecture M. Henri Becquerel exhibited an ingenious frictional electrical machine, devised by his demonstrator, M. Peignot. Mecrury is forced by means of a pump through the pores of a piece of chamois leather, and electricity in considerable quantities is generated by the friction. Ducretet, the well-known Paris instrument maker, has just finished a machine of this kind for the Conservatoire. The column of mercury is 1 metre high and 30 centimetres in diameter.

Prof. von Helmholtz.—Prof. von Helmholtz celebrated his 70th birthday on Monday. He was the recipient of numerous addresses and presents from learned societies in all parts of Germany. The congratulations of the Government were presented by the Minister of Public Worship. The University of Berlin was represented by the Rector, Prof. Förster; and the learned societies of London, Paris, Stockholm, Rome, Turin, Berne, and Vienna also sent their congratulations. In the evening a banquet took place in the Kaiserhof Hotel, which was attended by over 500 guests.

The Paris Municipal Station.—For some time past there have been vigorous complaints with regard to the irregularity of the current supply from and bad sanitary condition of the Paris Municipality's Central Station at the Halles. After several interpellations on the subject, the Conseil Municipal last week voted £640 towards improving the ventilation of the station. With regard to the irregular supply, it seems that the dynamos are overloaded, and accumulators are needed to cope with the demand for current during the busy hours. Meanwhile no more customers are to be connected up.

Lighting Circuits on Electric Railways.—The Cleveland Electric Railway Company is prepared to do electric lighting, and is negotiating with the municipal authorities for the illumination of the 50 miles of streets through which their lines run. "It seems to us," says the *Electrical Engineer* of New York, referring to this new development, "that in many cases the undertaking of street lighting service will enable the railway companies not only to keep more cars going, but to operate all around the clock. Thus, with a service to stationary motors during the day, and to arc lamps at night, the Electric Railway Company will see the curve of its load diagram flattened out at a high level of amperes with an exhilarating increase in the margin of profit."

Chicago Exhibition.—The Committee of the Polytechnic Institution (Regent-street) are arranging for co-operative excursions to the Chicago Exhibition in 1893, specially intended for working men and others whose means will not permit of visiting the New World under ordinary circumstances. The authorities have already entered into a contract with the Inman Steamship Company, by which means those who participate in these excursions will travel by the fastest vessels afloat; parties will leave Liverpool weekly during the months of June, July, and early part of August. The whole tour will be accomplished within one month. The Committee hope that the whole round excursion, including accommodation for the period, will not exceed 25 guineas. Already over half the places have been applied for.

The Electric Railway from a Sociological Point of View.—In a Paper recently read before the Thomson Scientific Club Lynn (Mass.), Mr. Oscar T. Crosby indulged in a good deal of statistic weaving. Assuming that the 33,700 electric cars now running in the United States make 490,000,000 miles per annum, and taking the economy to be four cents per car mile, Mr. Crosby estimates that society saves $19,600,000 per annum. He further estimates that there are 115,000 street railway stockholders in the United States, affected favourably in their incomes, ways of life, and ability to promote enterprises, by the higher returns from electric roads. To make the car mileage above mentioned there must be burned about 900,000 tons of coal. In all, some 80,000 individuals will, according to Mr. Crosby, be diverted within the next decade from their present occupations to those connected with electric railway work.

The Proposed Waterloo Station-Mansion House Subway.—In connection with this proposed electric subway railway, *Herapath's Railway Journal* states that about ten years back notices were given for two new independent lines from Waterloo into the City. The South-Western Company's engineer, Mr. Jacomb, then estimated roughly the cost of one of the projected lines at about £800,000 for construction and £1,500,000 for property. The cost of the proposed electric subway will not exceed £500,000. It is not proposed to slavishly follow the features of the City and South London Railway. The traffic from Waterloo to the City is purely for business men, and the time occupied would be about four minutes, with no intermediate stations. The promoters expect that they will come out within a few yards of the terminus of the Central London Railway which was authorised last year. A short subway would connect the two.

Annual Dinner of the Institution of Electrical Engineers.—We are informed by the secretary that amongst the guests who have accepted invitations to be present at the dinner are—The Postmaster-General (Sir J. Ferguson, Bart.), the Inspector-General of Fortifications (Major-General Grant), Sir G. G. Stokes, Bart., M.P. (late P.R.S.); Sir John Pender, Sir Thomas Blomefield (Board of Trade), Captain W. J. L. Wharton, R.N. (Hydrographer to the Admiralty); the Presidents of the following societies: the Institution of Civil Engineers, the Institution of Mechanical Engineers, the Iron and Steel Institute; Mr. Harrison Hayter, Mr. Alfred Giles, Sir Benjamin Baker, Dr. William Pole, Colonel W. Haywood (Engineer to the Commissioners of Sewers), and Mr. H. J. Chaney (Standards Department, Board of Trade).

Old Students' Association.—The seventh annual dinner of this Association was held on Saturday evening last at the Holborn Restaurant, under the presidency of Mr. W. B. Esson, some 60 members and their friends being present. The toast of "The Colleges of the City and Guilds of London Institute" was proposed by Mr. L. B. Atkinson, Dr. W. E. Sumpner responding. Mr. Albion T. Snell proposed "The Professors"; and in response to this toast Prof. Silvanus Thompson made an interesting speech, detailing the growth of the Institute since its inception. In the course of the proceedings the President announced that the ballot of members had resulted in his re-election; and that Mr. E. B. Vignoles had been awarded the Association medal for his Paper entitled, "Some Researches in Electro-magnetic Induction." Prof. Perry, owing to illness, and Mr. W. H. Preece, owing to another pressing engagement, were unable to be present.

Society of Arts.—The arrangements for the meetings of this Society during the ensuing Session have just been announced. The first meeting will be held on Wednesday, November 18th, when the opening address will be delivered by the Attorney-General, Chairman of the Council. On the following Wednesday evenings previous to Christmas Papers will be read on "The Measurement of Lenses," by Prof. Silvanus P. Thompson; on "The World's Fair at Chicago in 1893," by Mr. James Dredge; on "Secondary Batteries," by Mr. G. H. Robertson; and on "Spontaneous Ignition of Coal and its Prevention," by Prof. Vivian Lewes. Among the Cantor courses are lectures on "Electrical Distribution," by Prof. Forbes; and "The Uses of Petroleum in Prime Movers," by Prof. W. Robinson. A special course of lectures has also been arranged, under the Howard bequest, on "The Development and Transmission of Power from Central Stations," by Prof. W. Cawthorne Unwin, F.R.S., commencing shortly after Christmas.

Conventional Electricity.—There are, says *Industries*, many curious ideas which linger in the academic mind, and will, it is to be feared, never be eradicated. For instance, probably nine-tenths of the writers of text-books appear to think that electrical engineers use sine and tangent galvanometers for measuring, let us say, dynamo currents. Another established idea is that dynamos have something called a "critical speed," and that dynamo makers experiment to determine it. We have known makers turn out dynamos by the hundred without knowing what a critical speed may be. Of course we do not pretend to know either. Again, makers have worked for years to design voltmeters and ampere meters to give proportional readings. It is needless to remark that voltmeters should have their scales spread out near the standard pressures, while ampere meters should have similar scales for some purposes, and logarithmic scales for others. No instrument has yet been designed to give a logarithmic scale. The back electromotive force of the arc is now an old-established and eminently respectable phenomenon. Yet an electro-chemical pressure of thirty odd (very odd) volts is extreme, and there is no evidence to show that the conductivity of the arc does not vary as the cross section, and approximately as the current.

Obituary.—We regret to announce the death of Mr. William Fereday Bottomley. He commenced his career some 37 years ago in the service of the old Magnetic Telegraph Company. On the purchase of the telegraphs by the Government he joined the telegraph staff of the Lancashire and Yorkshire Railway Company with the late Mr. Warburton. Subsequently he undertook the management of the Manchester district for the Indo-European Company, which position he afterwards resigned to become one of the pioneers of practical telephony, and it was under his supervision that probably the first telephonic trunk lines in this country were erected. These were between Manchester and Stockport and Manchester and Oldham, and in this connection it is interesting to note that in these lines the now well-known "twisted wire" system, of which Mr. Bottomley, the late Mr. Charles Moseley, and Mr. W. E. Heys were the joint patentees, was first employed. As manager for Mr. Moseley, Mr. Bottomley, by his pleasant persuasions and by interesting public lectures, popularised the telephone in his district at an early date, and made the success of a telephone exchange which Mr. Moseley was about to establish a foregone conclusion. Mr. Bottomley next joined the National Telephone Company as their London Superintendent, but a few months afterwards the resignation of Mr. Butterworth having left the management of the Dublin Telephone Exchange vacant, Mr. Bottomley was appointed to the office, which he held and filled with great success until his death. At the commencement of his career he quickly gained the confidence of his chiefs, and being one of the most expert operators of his day, he easily won his way upwards; and it is highly probable that had he the high educational advantages which some of his colleagues possessed, his sound judgment, energy, and genial manner would have won for him a still more distinguished place. Mr. Bottomley died at the comparatively early age of 51, and leaves a widow and several children.

Effect of the Electric Light on Plants.—The results of some experiments on the influence of the electric arc lamps on plants in hothouses have been published by the authorities of the Cornell University Agricultural Experiment Station. The experiments were carried on during the winter of 1889-90, by introducing an ordinary arc of nominal 2,000 c.p. lamp into a house set apart for the purpose. This house was 60ft. long and 20ft. wide, and was divided into two equal portions by wooden partitions, so that one half might be kept dark during the night, while the other enjoyed sunlight during the day, and was kept lighted by the electric lamp at night. The electric lamp was suspended from the ridge of the house, just 2½ft. above the soil of one of four benches just below it. During the first six weeks commencing January 23, 1890, the light was naked, but during the rest of the time up to April 12th it was covered by an ordinary white opal globe. While the light was kept naked it showed a marked influence in hastening the maturity of such leaf plants as endive, spinach, cress, and lettuce. This was the more marked the nearer they were to the light, and the leaves were small and more or less curled or injured close to it. Notwithstanding this, they contained the same amount of starch as leaves of plants at a greater distance from the light, but the grains were larger and better developed. The result was that the plants ran to seed without forming leaves large enough to be useful for table purposes. The other division of the house, lighted by sunshine only during the day, was planted at the same time for comparison with that under the influence of the electric light. Within 3ft. of the lamp on either side the plants were killed outright, while all the rest were seriously crippled in the lighted house. Peas were most fruitful in the dark house, lettuce was fifty per cent. better at the end of three weeks in the light house than in the other, and was fit to cut in a month, while that in the dark house took a fortnight longer to grow to the same size. The colours of various tulips were intensified, but faded again in the course of four or five days. Varieties of coleus gave rise to some interesting facts. After two nights, within 3ft. of the lamp, the red sorts became yellow, brown became green, green lost its brightness, and dark purple became glossy-black. The shaded portions of the leaves remained unchanged, so that with daylight the exact outline of the shaded portion could be easily defined for some days afterwards. So varied have been the results with different plants under different conditions, that it is evident many more experiments must be made before any definite conclusion can be arrived at, as to whether the electric light can be put to any practicable and useful purpose with profit. This will form the object of future experiments which are to be undertaken.

MAGNETISM IN IRON AND OTHER METALS.*—LV.

BY PROF. J. A. EWING, F.R.S.

(*Concluded from page 685, Vol. XXVII.*)

§ 187. **Effects of Elastic Strain.** — In previous articles (§§ 120—142) an account has been given of experiments made to investigate the effects of stress on the magnetic quality of iron and the other magnetic metals. Without attempting any full discussion of these results from the point of view which the molecular theory affords, we may refer to one or two general features where a molecular explanation seems comparatively easy.

That stress should produce an influence on magnetic quality is a probable result of the strain to which the stress gives rise. The effect of a simple longitudinal stress is, as we have seen, to make the metal, originally isotropic in its magnetic quality, become æolotropic, and it may be conjectured that this happens through differences becoming established in the pitch of the molecular magnets, in lines respectively along and across the direction of the stress, whereby old lines of molecules break up and new lines are formed. A uniform dilation or a uniform compression (with equal intensities of stress in all directions) might be expected to have a much less considerable influence on magnetic quality than a simple stress has. Experiments on the effects of such stresses are wanting; it may be anticipated that effects resembling those due to change of temperature would be observed. Thus we might expect to find a uniform pressure in all directions associated with a general reduction of magnetic susceptibility. The experiment would be an interesting one to carry out, especially in nickel, where (§ 122) the susceptibility is known to be greatly increased by a single stress of compression applied in the direction of magnetisation.

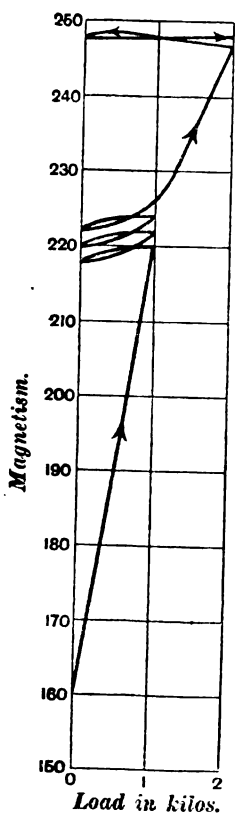

Fig. 157.—Effects of Loading a Soft Iron Wire in a Weak Magnetic Field.

A stress of simple pull will lengthen those rows of molecules which lie more or less along the axis of the stress, and will shorten those rows which lie more or less across the axis. This is enough of itself to develop differences of magnetic susceptibility in the longitudinal and transverse directions; and the difference is probably much enhanced by a re-arrangement of the molecular rows, the longitudinal rows being more or less broken up and transverse rows formed. The lengthening of the longitudinal rows will tend to increase the susceptibility; the shortening of the transverse rows, and still more the secondary consequence of stress, namely, the formation of new transverse rows, will tend to reduce it. It seems that in nickel the latter effect is the dominant one; in iron, on the other hand, we find a conflict of influences which makes pull favourable or otherwise according as the magnetisation is less or greater than a critical value.

The large magnetic changes due to torsion, which are seen in experiments in nickel, such as the reversal of magnetism which Nagaoka found when a loaded nickel wire is twisted to and fro to alternate sides (§ 142)—appear to be secondary effects, due to the reconstruction of molecular rows which become unstable when the molecular centres are displaced by the strain. It is the existing magnetism of the piece that is being affected, rather than its susceptibility to induction by the field.

An obvious conclusion from the molecular theory is that there should be, as we know there is, hysteresis in the changes of magnetic quality that are associated with changes of stress, and also that the condition arrived at by applying a load first and then magnetising should in general be different from the condition arrived at by first magnetising and then applying a load. (*See* §§ 120—131).

Another fact which the molecular theory serves to explain is the important difference which experiments reveal between the effect that is produced by the first application of a stress, and the effect that is produced when the same stress is applied after it has been previously applied and removed many times. After what has been said above in § 127, a brief reference to this matter will suffice. Provided the magnetising force is not very strong, the first application of load, when the piece hangs in a steady magnetic field, upsets molecules which were nearly upset before the load was applied. Removal of the load does not make these molecules recover the position from which the application of the load disturbed them. Thus successive loadings and unloadings, especially in a weak field, serve, as it were, to shake in the magnetism; and, if residual magnetism is dealt with, the field having been removed, successive loadings and unloadings serve to shake it out. Examples of this have already been given in Figs. 108 and 109, where the effects of a first loading and unloading are readily distinguishable from those that occur after a cyclic régime has become established by repetition of the cycle of loads. In strong fields, as the theory would lead us to expect, the cyclic régime is quickly attained; a second loading is enough to show that the initial disturbing influence of the stress is exhausted. In weak fields, the loading has to be repeated many times before that is the case, and the first disturbance is sometimes immensely greater than the alteration of magnetism that accompanies each application and removal of the load after a cyclic condition has been reached. Fig. 157 gives an example. The specimen dealt with there was a long wire of soft annealed iron, 0·76mm. in diameter, which hung in a weak field ($H = 0{\cdot}34$). A load of 1 kilogramme applied for the first time raised the magnetism from 159 to 220 (in arbitrary units). Removal of the load reduced it only to 218. Reapplication brought it up to 222; a second removal reduced it to 220¼. A third application made it 224, a third removal 222, and a fourth application 225½. Then the load was increased to 2 kilogrammes, and the magnetism went up at a bound to 247, when again successive unloadings and loadings produced but slight changes which tended gradually to assume a cyclic character when the operation was repeated many times.*

§ 188. **Hysteresis in Changes of Molecular Configuration, apart from the Existence of Magnetisation.**—In §§ 133-135 experiments have been referred to which show that when iron is subjected to cyclic variation of stress, its structure undergoes changes that involve hysteresis, even when no magnetic force acts upon it, and there is no magnetisation of the piece as a whole. The molecular theory makes the reason of this sufficiently apparent. Elastic strain brings about a rearrangement of the molecular grouping; old combinations break up and novel combinations are formed, although no magnetic forces are concerned other than the forces which the molecuiar magnets exert on one another. These changes of configuration involve unstable movements on the part of the molecules, and hysteresis consequently manifests itself, when the piece is carried through a cycle of strain. We find, for instance, that when an iron wire under tension is loaded and unloaded, by putting on and taking off weights, there is a distinct difference in the physical state of the metal, under one and the same intermediate amount of weight, during loading and during unloading. The difference shows itself in magnetic susceptibility, in thermo-electric quality,† and possibly in many other physical qualities of the material. It continues to be found when the cycle of loading is repeated, and its character is just such as the molecular theory would lead us to expect.

This hysteresis in molecular configuration, apart from all actual magnetisation, which exhibits itself when the piece is carried through a cycle of elastic strain, has one important consequence. It implies that the elasticity of the substance is not perfect. The unstable movements of the molecules, to

* All rights reserved.

* For details of this and other experiments illustrating the point now referred to, see *Phil. Trans.*, 1885, p. 594, *et seq.*

† See *Phil. Trans.*, 1886, p. 361.

Digitized by Google

which it is to be ascribed, result in a dissipation of energy. More work has, therefore, to be spent in stretching the piece, while loads are being put on, than is recovered when the loads are taken off—in other words, the stress that corresponds to any given intermediate value of the strain must be greater during the application of the load than during its removal. There must be hysteresis in the relation of strain to stress; and, as we have seen already (§ 135), this conclusion is borne out by experiment.

§ 189. **Experimental Study of Molecular Groups by means of Models.**—It is extremely helpful, in considering the constraint which the molecular magnets suffer in consequence of their polar forces, to experiment with a model consisting of a

Fig. 158.

number of short steel magnets, pivoted like compass needles on fixed centres, and placed near enough to one another to allow the mutual control to be felt.* Such a model is readily made out of pieces of stout magnetised steel wire, bent, as in Fig. 158, to bring the centre of gravity below the pivot point. A recess for the pivot is stamped by a centre punch in the hollow of the bend, and the pivot itself is a needle stuck, with the point

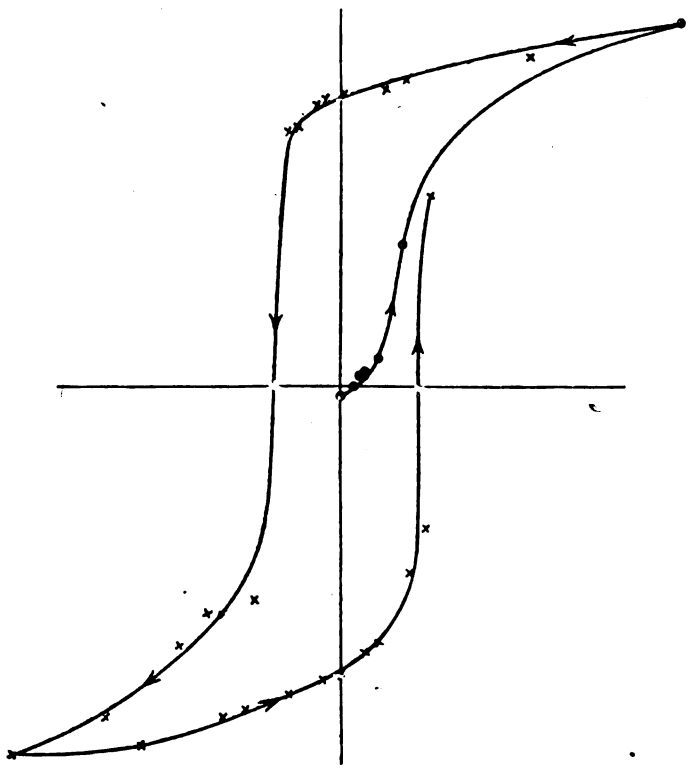

Fig. 159.—Cyclic Process applied to a Group of Twenty-four Pivotted Magnets.

upwards, in a small block of lead or of wood. Instead of a wire, a piece of steel plate may be used for the magnet, and this may have any form given to its polar extremities, from sharp points to semicircles. The magnets being of hard steel, strongly magnetised, are practically unaffected (as to the intensity of their magnetism) by the comparatively weak external magnetic forces which one applies to turn them into line. The external force may be applied by a coil wound in an open manner over a light framework, within which the group of magnets is placed, the open winding allowing the behaviour of the magnets within to be observed. Or a larger coil placed entirely underneath the group may be used; or, better still, a pair of closely-wound short coils placed one on either side of the group. This last form is especially convenient when the behaviour of the group is to be exhibited by projecting them on a lantern screen. For that purpose short magnets are necessary, and the magnets used for small pocket compasses will be found very suitable; the pivots themselves may also be cut out of such compasses and cemented, at proper distances, on a glass plate. To exhibit the effects of strain, the pivots may be arranged on a framework of jointed wooden rods, forming two crossed sets of parallel lines; by placing the pivots at the joints, or midway between the joints, some of the effects of simple shear or simple pull and push may be studied.

A model of this kind allows the three stages of the magnetising process to be readily distinguished. The phenomena attending reversal of magnetism, the dissipation of energy in hysteresis, the conditions that promote residual magnetism, the comparative effects of slow and sudden changes in magnetic force, the primitive and final effects of strain, the influence of vibration, the existence of time-lag, are all matters of which the model gives effective illustration.

The manner in which the resultant polarity of the group of pivoted magnets changes when the field is applied, reversed, or varied in any way, is sufficiently evident on mere inspection of the group. It may, however, be determined quantitatively by using a magnetometer in the ordinary way, taking care to compensate for the action of the coil which supplies the magnetic field by placing in series with it a second coil, the position of which is adjusted to annul the deflection which the first coil by itself would produce. A group of magnets examined in this way, when carried through a cycle of configuration by applying and reversing the directive force of the coil, gives what we may call curves of magnetisation, in which all the main characteristics of the ordinary curves for iron appear, though, of course, the limited number of magnets which it is practicable to use in such an experiment makes the steps of the process more jerky than they are when we have to deal with the multitudes of molecules in a piece of solid metal. Curves obtained by this means, showing the reversal of a group of twenty-four little magnets (like Fig. 158) under reversal of the directing field, are given in Fig. 159.*

§ 190. **Ampère's Hypothesis as to the Nature of the Magnetic Molecules.**—Granting, as we very well may (in view of the considerations summarised in this chapter), that the process of magnetising consists in turning round molecules that are already magnetic, so that their axes tend, under the directing force of the applied field, to approach a particular direction, the question still remains, to what is the primitive magnetism of the molecules due? Weber's theory does not help us to an explanation of the fact, which it postulates, that each molecule is a permanent magnet.

According to the hypothesis of Ampère the magnetism of the molecule is due to an electric current continually circulating within it—in other words, the molecule is a conducting circuit in which a current flows, and when a directing field acts, the channel in which this current flows tends to set itself at right angles to the direction of the field, just as does the coil of an electro-dynamometer. Ampère's theory, therefore, explains all the phenomena of magnetisation as consequences of the mutual action of electric currents. According to it, in magnetising a piece of iron we are dealing with the forces which exist between the current in an external conductor and the currents in molecular circuits within the metal, which are prevented from immediately putting themselves into perfect parallelism with the external circuit only because of the forces which the currents in the molecules exert on one another. In this view the model of a magnetic metal should be constructed, by using not pieces of permanently magnetised steel to represent the molecules, but little coils, free to turn, in each of which an electric current flows continually.

*Proc. Roy. Soc., 1890, Vol. XLVIII., p. 342; *Phil. Mag.*, September, 1890

* Fig. 159, for which the author is indebted to Mr. Glazebrook, represents the results of an experiment by Mr. J. W. Capstick, made in answer to a question set in the practical examination of the Cambridge Natural Science Tripos, 1891. Curves of this kind were first published by Mr. Arthur Hoopes in the *Electrical World* (New York), May, 1891. See *The Electrician*, May 29, 1891.

Digitized by Google

The molecular channels must be supposed to offer no resistance as conductors, otherwise the primitive currents would require energy to be expended in maintaining them.

When a field is applied it tends to turn the molecular circuits, and it also induces supplementary currents in them. These induced currents are superposed on the primitive currents; their strength depends on the inclination of the circuit to the field; and their general effect is to reduce the primitive currents. Whether they will do so to any great extent depends on the area and the self-induction of the molecular circuits, and on the primitive strength of the currents in them.* Thus if the primitive currents are strong and the other conditions favourable, very little reduction of the primitive strength takes place through this induction of current by the applied field. In that case the molecular circuits are nearly equivalent to strictly permanent magnets, and merely turn in response to the field, without suffering any material loss of intensity. Probably this represents what occurs when iron or any of the other strongly magnetic metals is magnetised.

When the primitive molecular currents are weak the induction of opposing currents by the application of a magnetic field may modify the resultant strength very greatly; and in particular, when there are no primitive currents at all, but only conducting molecules ready to have currents induced in them, the application of the field will induce currents which give to the piece a polarity of the kind opposite to that which it acquires in ordinary magnetisation. By recognising the existence of these induced currents Weber thus extended Ampère's theory of molecular conducting circuits to account for *diamagnetism*.

But even when there are strong primitive currents, as we must suppose there are in the molecules of iron, the induction of opposing currents, in consequence of applying a magnetic field, will go on to some extent, and there is a stage at which its influence may be appreciable. This is when the piece is saturated—when all the molecular circuits are turned into planes perpendicular to the direction of the field. In that position they are as favourably placed as possible for the induction in them of currents opposed to the primitive currents. When the field is further strengthened, the resultant current in each molecular channel is reduced, and as the channels are already all perpendicular to the field, the only effect of increasing the field is to reduce the magnetisation by reducing the strength of each molecule. The Ampère-Weber theory, therefore, leads us to conceive of the magnetism of iron as tending to pass a limiting value when saturation is reached, after which a stronger magnetising force should actually weaken the magnetism. The results of experiments with very strong fields neither confirm this nor contradict it. They show that when the condition of saturation has been approached the field may be strengthened ten-fold or more without any material change in the magnetisation, either in the way of addition or loss. But the conditions under which those experiments are carried out make very accurate measurement impracticable, and a small reduction of the magnetism might pass undetected. It is probable enough that stronger fields still must be used to discover it, for the reduction to be expected as a consequence of induced currents in the molecular channels is slight at the most, and in the approach to saturation which is long drawn out, the continued deflection of the molecules tends to counterbalance any effect that may be produced by a small loss of moment on the part of each.

GERMAN GAS AND ELECTRIC LIGHT STATISTICS.

BY CLARENCE FELDMANN.

Under the title of "How shall we build our central stations?" Herr Friedrich Ross, Director of the Helios Company of Ehrenfeld, has published a pamphlet written especially for municipal authorities. The author states in the preface that he is a partisan of the alternate-current transformer system, and then gives some details of a few German central stations working with accumulators, from which I extract the following:—The central station of Barmen delivered to the mains from the 1st of May, 1890, till the 10th of the same month 1,771,653 watt-hours, the total output of the dynamos being 2,681,970 watt-hours. The charge of the accumulators was 1,759,731 watt-hours, and their discharge 547,356, giving a mean efficiency of 37 per cent. Shortly afterwards the battery had to be reconstructed on account of buckling of the plates. From the 20th to the 28th of September, 1890, the efficiency amounted to 55·8 per cent., the total output of the dynamos being 3,769 kilowatt-hours, and the consumption in the network 2,985 kilowatt-hours, the accumulator charge 1,784 kilowatt-hours, and the discharge 996·5 kilowatt-hours. Similarly the mean efficiency of the central station of Darmstadt was 38·6 per cent. in 1889 and 55·9 per cent. in 1890, after the accumulators had been reconstructed towards the end of August, 1889.

All central stations working with accumulators have been planned on the assumption of a rather low number of hours of daily maximum consumption; and the author asserts that such statements are erroneous, or are so in most cases. He shows from the gaswork statistics of 24 of the largest German gasworks that the gas supply for heating and power purposes amounts to only 6½ per cent. of the total output, and that for 16 other gasworks the hours of heavy consumption were, on an average, 8·7. Another table contains the maximum consumption in one day, and in one hour of this day, for several electric stations, and shows the quotient of these two quantities, which gives the hours of maximum load: Berlin, 8·8; Barmen, 6·9; Elberfeld, 5·6; Hamburg, 8·2.

Some interesting details of the Düsseldorf central station are then given. It is stated, among other things, that in Darmstadt the total length of gas main is about 116 kilometres for, approximately, 35,000 gas lights, or 3·3 metres of main per gas burner, corresponding to one 16 candle-power lamp. The electric network is planned with about 32 kilometres of mains for about 20,000 16 candle-power lamps, or with 1·6 metres of mains per lamp. For the central stations of Darmstadt and Elberfeld Herr Ross gives the cost of current production per 16 candle-power lamp-hour as 2·45 and 1·33 pfennigs (one pfennig = ·12d.) respectively, the annual cost per lamp being 3·55 marks in Darmstadt and 4·8 marks in Elberfeld. For these two stations the maximum consumption is nearly equal, but the average annual number of lamp-hours is 289 in Darmstadt and 730 in Elberfeld.

In the last table are given some average values for the annual lamp-hours, the length of main per light, and the ratio of daily maxima to total lamps installed, all calculated from the statistics of 35 gasworks of various sizes; these three numbers varying from 1,610 to 1,270 hours; 2·49 to 4·4 metres, and 50 to 57 per cent.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

FRIDAY, November 6th. (To-night.)

PHYSICAL SOCIETY.

5 p.m. Paper to be read on "Corresponding Temperatures, Pressures, and Volumes." By Prof. Sydney Young.

TUESDAY, November 10th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meetings. Address by the President, and Presentation of Medals, Premiums, and Prizes awarded during last Session.

THURSDAY, November 12th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting. Paper to be read, "Description of the Standard Volt and Ampere Meter used at the Ferry Works, Thames Ditton." By Capt. H. R. Sankey and F. V. Andersen.

FRIDAY, November 13th.

INSTITUTION OF ELECTRICAL ENGINEERS.

7 p.m. Annual Dinner at the Criterion Restaurant, Piccadilly.

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday.*

SMALL ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1891 Edition, published on the 23rd February, 1891, consists of 900 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with well-written Biographical Notices of leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

A few copies of the issue for 1891 remain, price 4s., post free 4s. 9d. Abroad postage extra. Prospectuses and full particulars free.

ELECTRICAL BOOKS AND PUBLICATIONS

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

MODERN MAGNETIC SCIENCE.

If it were desired to illustrate the truly radical changes which have swept over experimental science during the past twenty years it would be scarcely possible to select a more striking example than that afforded by the science of magnetism. Only ten years ago the old terms derived from the ancient action-at-a-distance ideas were in vogue, and magnetic poles with their supposed surface-distribution of the imaginary magnetic fluid or fluids were the all-in-all of this branch of science. This was quite sufficient for the requirements of the ordinary examiner of the University; it was susceptible of being decked out with an endless array of mathematical symbols. The differential equations for the forces between two poles at a distance being once established, it was a fine exercise for the expert mathematician to evolve from his imagination some supposed law of surface distribution, and then duly to work out the integration of his symbols to find the

Digitized by Google

resulting force. But this was all so much elegant beating of the air. His array of symbols corresponded to nothing real either in the heavens above or in the earth beneath. The species of magnetism thus mathematically evolved differed widely from the actual magnetism which the practical man had to deal with in the industries, whether for telegraphic relays or for dynamo-machines. The real magnetism obstinately refused to distribute itself in accordance with the sextuple integrals of the mathematician, or to walk along the exquisite scaffolding of the three rectangular co-ordinates which he had painfully erected. One thing had unfortunately been left out of sight by the abstract mathematicians in their treatment of magnetism; but that one thing was precisely the most important fact of all. They had quite lost sight of the magnetic properties of the materials. They were looking at the magnet from the outside only, instead of considering the internal conditions, of which the so-called poles are only the external, and, as it were, the accidental manifestations. True they used, in a vague way, the term "coercive force," to express some sort of a property of the material, by virtue of which it kept the two supposed magnetic fluids from following their own natural tendency to run together and neutralise one another. But what the coercive force was they could not tell us, nor how much it was; nor could they give any rational account of the alleged fluids.

All this old and semi-metaphysical stuff has gone for ever. The modern science of magnetism begins where the older science left off—with the properties of the materials. It is with the properties of the materials, their permeability, their retentivity, and their hysteresis, and the variations of these properties under varied physical conditions, such as temperature and stress, that modern magnetic science deals. Hundreds of different brands of iron and steel have been now examined to ascertain their magnetic properties under all possible conditions. They have been subjected to all possible degrees of magnetising force from the strongest to the weakest; sometimes slowly, sometimes in rapidly recurring cycles. They have been heated and cooled, compressed and elongated, twisted, vibrated, and laminated; with the result that our present knowledge of the facts of internal magnetism is marvellously complete. We have learned, in fact, to look at a magnet from the inside instead of the outside, and know what the inside facts are.

In this great advance many workers have contributed to the accumulating stock of knowledge. But amongst them there is one whose ten years of self-imposed labour will never be forgotten, namely Prof. Ewing, from whose pen a series of articles on magnetism have been flowing in the columns of this journal throughout the past twenty months. We take the occasion of the publication to-day of the concluding article of his series to point out the invaluable services which Prof. Ewing has rendered to the electrical world by his work in a field which he has made so peculiarly his own. Had he performed no other service than to examine the phenomena of hysteresis, and to coin for us that most useful name to denote the group of facts for which a name was so long wanted, he would have earned the gratitude of every worker in magnetism. Had he done nothing more than investigate the effects on magnetism of compression, tension, and torsion, he would have assuredly gone down to scientific posterity for his careful and intelligent unravelling of the complex phenomena exhibited by magnetic substances in these relations. Had he never done anything else than produce that brilliant bit of speculation, the molecular theory of magnetism, by the aid of which he is able to explain so many of the more obscure facts without calling in the aid of adventitious internal frictional forces, he would have justly earned a scientific renown. But even so, he would have only been, so to speak, the equal of the Hopkinsons, the Warburgs, the Rowlands, the Bosanquets, the Bidwells, and the Tomlinsons who also have made valuable scientific investigations in kindred matters. But Prof. Ewing had done one thing more which none of these other investigators have done; he has given to the wider world of workers the opportunity of learning for themselves what these various researches are, and to what they lead. Other investigators have been content to consign their results to the sacred custody of the *Transactions* or *Proceedings* of the Royal Society or other learned body, where they remain practically buried for the vast majority of electrical engineers. How many of our readers have ever seen the original memoirs of Mr. Bidwell we do not know. How many of them ever heard of the hundred and seventy-page quarto of Mr. Tomlinson's work we scarcely dare to inquire. And how many of them would know of Prof. Hopkinson's work, if it had not been published elsewhere than in the *Philosophical Transactions*, we need not ask.

It seems to us, indeed, that the Royal Society itself is not free from blame in the extreme inaccessibility which it throws around its most important publications. Why it should charge such absurdly high prices for the memoirs it prints is a conundrum only to be answered by asking another: Why it prints so few copies that the price must necessarily be high? Surely a body so highly endowed cannot wish to make trading profits on its publications. The memoirs of Ewing alone, as published by the Royal Society, cost 16s., whilst a single one of Hopkinson's is charged 7s. In the face of such prices one might almost suppose that the Royal Society was anxious that the memoirs it publishes should not be read by any outsiders.

Professor Ewing has, however, come to the rescue. In the articles which we have had the honour of publishing, he has set forth, in simple, straightforward language, the work which he and other investigators have done to enrich magnetic science. And, in thus placing the rich stores of his information at the disposal of a wide circle outside the narrow limits of the scientific societies, he has conferred a real and lasting boon upon the electrical fraternity throughout the world.

THE FRANKFORT EXHIBITION.—XVI.

(FROM OUR SPECIAL CORRESPONDENT.)

The Thomson-Houston exhibit attracted particular attention. A single cylinder 100 H.P. engine, by McIntosh and Seymour, drove a 40-kilowatt, 220-volt compound machine. In addition to this dynamo there was an ordinary Thomson-Houston arc lighter. From the compound machine wires were run to the Thomson-Houston pavilion, where the current drove a dynamo-motor. In addition to the fixed brushes there was a second rotating pair of brushes. This pair revolved at a speed of 325, the armature running at 1,600 revolutions. By means of this strange device one and the same machine can be made to give a continuous current, an alternating current of 325 ∿ per minute, and a pulsating current. The continuous current is taken off the fixed brushes, the alternating off the rotating brushes, and the pulsating current is obtained by using one or other of the two fixed brushes and one of the rotating brushes.

In Dr. Otten's recent Paper on "The Application of Electricity to Mining," † a number of applications to which these currents, continuous, alternating, and pulsating, may be put are considered in some detail; and it may be worth while to draw attention to the way in which the alternating and pulsating currents are employed in connection with the much-illustrated but little known Van Depoele reciprocating drill, which is exploited by the Thomson-Houston Company.

† Elek. Zeit. 12: 634 Nov 20, 1891

Digitized by Google

Three coils, 1, 2, 3 (*see* diagrammatic sketch, Fig. 1), are wound side by side and fixed firmly in an iron casing, an iron core, to one end of which the drill is fixed, being introduced into the coils. The two outer coils, 1 and 3, are in series, but oppositely wound so that the current passing through them produces an equal and opposite magnetising effect. The two outer coils are com-

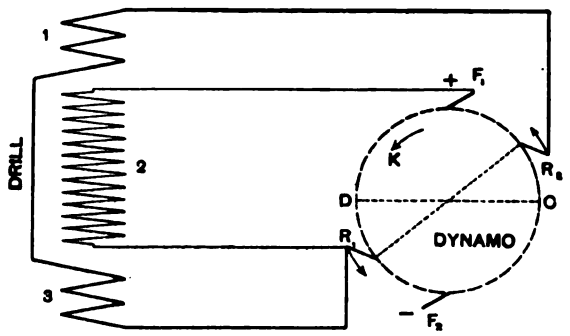

FIG. 1.—Van Depoele Reciprocating Electric Mining Drill. Connection of coils with source of power.

posed of a few turns of thick wire, while the middle coil, 2, consists of a large number of turns of fine wire; and it is this coil which has the chief magnetising effect. The method of circuiting the coils is shown in the figure, where F_1, F_2 are the fixed brushes and R_1, R_2 the rotating brushes. From this diagram it will be seen that the outer coils are connected in series with the rotating brushes $R_1 R_2$, and traversed therefore by an alternating current, the phases of which, neglecting for simplicity's sake the consideration of self and mutual induction, are substantially as shown by the thin curve (Fig. 2), while the inner coil is traversed by a pulsating current, the poles being the positive brush F_1 and the rotating brush R_1, the pulsations of the current being represented by the thick line in Fig. 2.

In the same diagram (Fig. 2), vertically under each of the points F_2, C, F_1, D, F_2, are sketched the corresponding polarities assumed by the two coils 1 and 3, and at the sides are also sketched the corresponding positions and polarities of the iron core I, the direction in which it is moving or tending to move being shown by the arrow heads. Starting at C, we have the outer coils 1 and 3 unexcited, and the iron core lies symmetrically with respect to them. Immediately after point C polarities are induced, as shown in the diagram, and are clearly such that coil 1 repels and coil 3 attracts I. As we move from C to F_1 the magnetism induced by the pulsating current round the core and iron casing dies away, so that the South pole of I, which is sucked down into coil 3, dies out, thus preventing the repulsive effect of the S pole of coil 3 then reaching its maximum. In this way I is pulled down with considerable force to the outer end of coil 3, the momentum of the core being destroyed by the drill striking the material worked upon. After

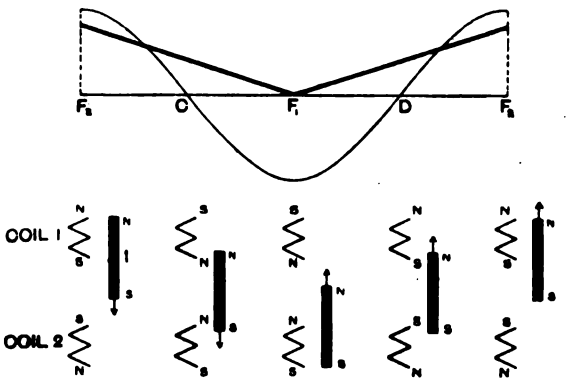

FIG. 2.—Van Depoele Reciprocating Electric Mining Drill. Phases of the pulsating and alternating currents supplied, and corresponding positions of the reciprocating iron core.

the point F_1 the magnetism of the core and of the casing (both unreversed) again grows. The three like (South) poles repel each other, and the core I is driven out of coil 3. After point D, it will be seen that the polarities of the coils 1 and 3 are reversed, so that I is drawn into coil 1. The magnetism of the core is, however, increasing, and reaches its maximum at the same time as that of coils, and three similar (North) poles approaching each other as the coil nears the outer end of coil 1, namely, those of the iron casing, of the core and of the coil; the core is brought to a stand without striking the end of the iron casing. The core I is then pushed out of coil 1 again, and the cycle repeated.

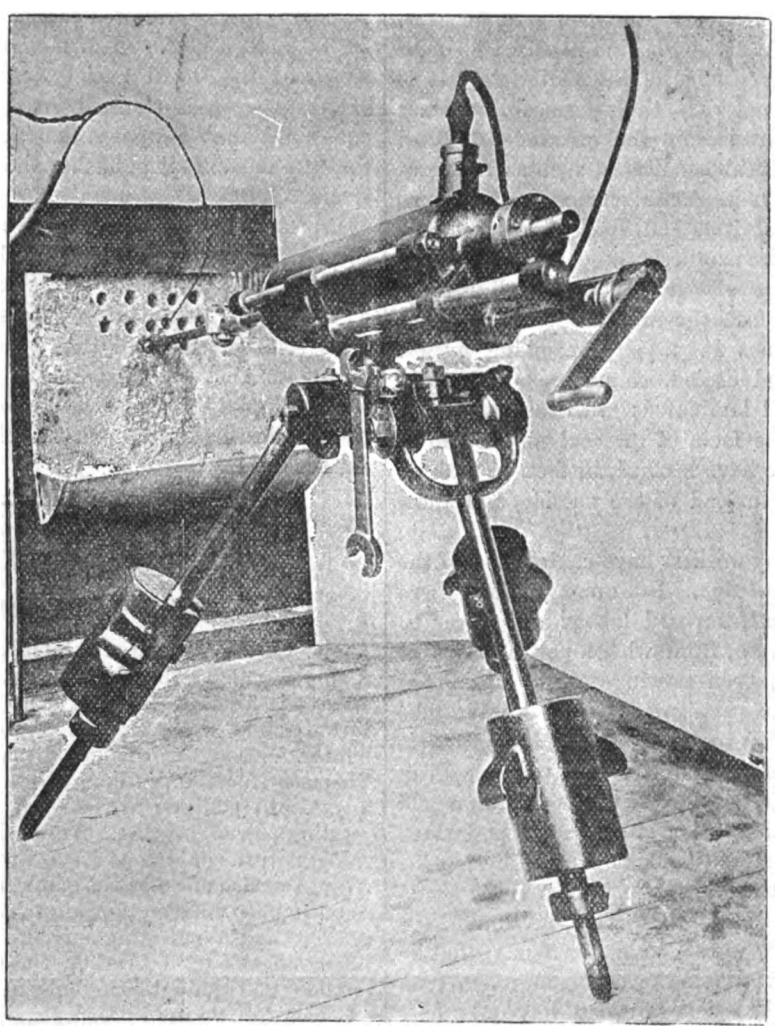

FIG. 3.—Van Depoele Reciprocating Electric Mining Drill. General view.

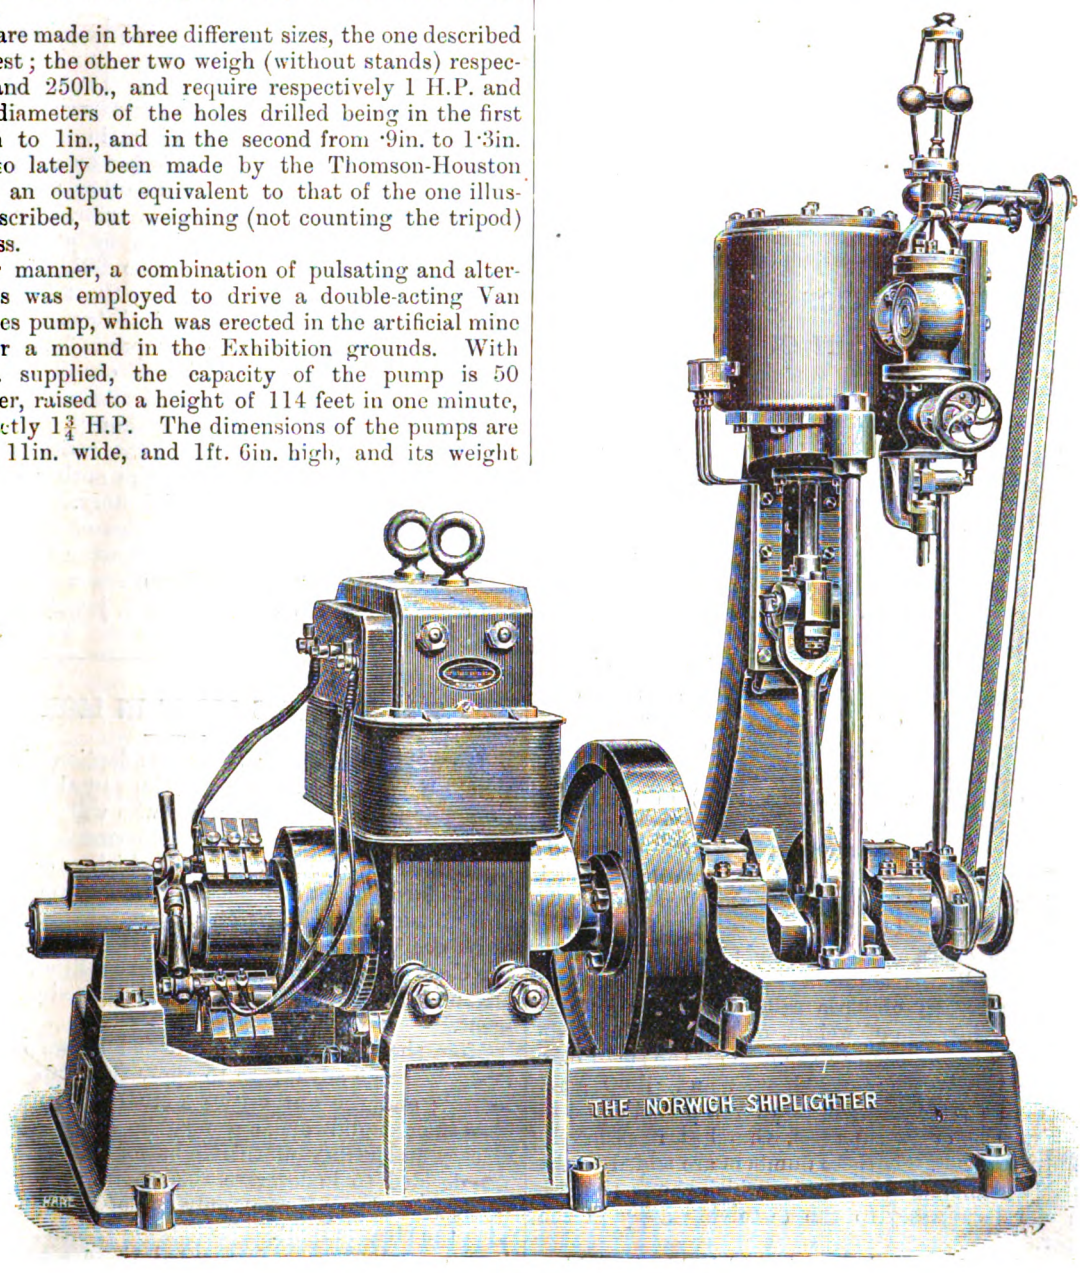
The number of strokes per minute is about 325. The length of the stroke is nearly 5½in., and at every stroke the drill turns automatically the eighth part of a revolution round its axis, so that the hole made is bored evenly out into a cylindrical form. The whole apparatus, which is shown in Fig. 3, stands on a tripod with weighted legs, easily set up, and all the man in charge has to do while drilling a hole is to keep slowly turning the lever handle shown in the illustration, in order to advance the instrument forward at the same rate as the hole is being bored, and to see that the material worked upon is supplied with water at the part operated on. The drill is of very solid and simple construction, and apparently not likely to get out of order or suffer much from rough treatment. The weight of the instrument, exclusive of the stand, is just over 4cwt., the stand, with the movable weights fastened on the legs, weighing

Digitized by Google

about the same. The power absorbed amounts to about 2 H.P. in drilling holes of from 1½in. to 2in. In hard granite the drill is said to be able to bore a hole 1·7in. diameter and 15¾in. deep in a space of ten minutes. In the experiments at Frankfort on Odenwald granite and gypsum the figure in the case of granite exceeded the above, and in the gypsum blocks holes of diameter 1·4in. and depths of 7·9in. were made in a minute when water was used, the depth, however, without water reaching only 4·7in.

These drills are made in three different sizes, the one described being the largest; the other two weigh (without stands) respectively 134lb. and 250lb., and require respectively 1 H.P. and 1¼ H.P., the diameters of the holes drilled being in the first case from ·4in to 1in., and in the second from ·9in. to 1·3in. A drill has also lately been made by the Thomson-Houston Company with an output equivalent to that of the one illustrated and described, but weighing (not counting the tripod) 28 per cent. less.

In a similar manner, a combination of pulsating and alternating currents was employed to drive a double-acting Van Depoele-Knowles pump, which was erected in the artificial mine arranged under a mound in the Exhibition grounds. With 2½ to 3 H.P. supplied, the capacity of the pump is 50 gallons of water, raised to a height of 114 feet in one minute, *i.e.*, almost exactly 1¾ H.P. The dimensions of the pumps are 3ft. 5in. long, 11in. wide, and 1ft. 6in. high, and its weight is about 7cwt., figures which speak well for its employment wherever space is an object.



Laurence and Scott's Shiplighting Set.

LAURENCE AND SCOTT'S SHIPLIGHTING SET.

The accompanying illustration represents one of Messrs. Laurence, Scott and Co.'s shiplighting sets, S.L. 5 type. The output of the one illustrated is 65 volts, 140 amperes, at 260 revolutions per minute. The engine is provided with very large bearing surfaces and ample lubricating arrangements, but otherwise calls for no special mention. The weight of the dynamo field-magnets is taken through brass packing pieces on two strong ribs that run across from one side to the other of the bedplate, whilst they are held in position by means of the Muntz metal studs coming through the strong brackets on the side of the bedplate, circular brass distance pieces being arranged between these brackets and the magnet poles. The armature of the dynamo is of Laurence, Scott and Co.'s usual type, the conductor being wound in slots milled into the plates which form the armature core. These plates have hexagon holes, into which the hexagon steel shaft is driven, with insulating pieces.

It is necessary that the width of the slots should not exceed a certain amount. In practice these makers find it should not be more than twice the clearance between the armature and the pole pieces. In the commutator of the above machine there are 110 sections, one turn of conductor to each section; but there are only 55 slots cut in the armature, each ·355in. wide. This would be an excessive width, but in winding each slot is made into two by means of three longitudinal strips of charcoal iron, running the whole depth and length of the slot, but insulated from both the conductor and the armature core. These strips reduce the width of each slot to ·14in., and thus make the outside surface of the armature sufficiently even magnetically to entirely do away with the heating of the pole pieces and the noise that would have been caused by the wider slots. The armature of the machine is 13⅛in. diameter outside, 11⅛in. at the bottom of the slot, and 9in. long. It is

Digitized by Google

wound with four parallels of No. 13 wire braided. The magnets call for no special mention. They are of Lowmoor iron, and have a sectional area of 85 square inches. The ampere turns in the shunt are 9,370, and in the series 7,840.

The set illustrated was worked up to 200 amperes for six hours before leaving the makers' works. Even with this very excessive load there was no sparking, and the rise of temperature in the armature at the end of the test was only 80°F. The makers have recently obtained a licence from Mr. Gisbert Kapp to use his patent end connections for bar armatures, and these will be used in the large machines. They have been making a large number of shiplighters for Scotland and the North of England during the last eighteen months. They have had an absolutely clean record with them, not a single breakdown having occurred up to date.

ON THE APPARENT VARIATION OF THE ELECTRO-CHEMICAL EQUIVALENT OF COPPER.*

BY M. VANNI.

Many investigators have called attention to, and Mr. Thomas Gray† has made a special study of, the influence which the current density at the cathode of a copper voltameter appears to exert on the electro-chemical equivalent of that metal as deduced from the increase of the weight of the negative electrode. The author proposed to himself to verify the hypothesis which attributes the observed variation to the dissolving action of the sulphate of copper solution on the copper.

In the experiments two voltameters in series were always employed. The negative electrodes consisted of sheets of copper of good commercial quality, covered with a layer of electrolytically deposited copper. The portion of the electrode in contact with the liquid had a surface of 58 sq. cms. (9 sq. in.) in one, and of 14·5 sq. cms. (2·25 sq. in.) in the other voltameter. The anodes were also sheets of copper, covered with a deposit. The weighings were carried to the half milligramme (·0075 grain). The sulphate of copper solutions had a density of 1·12; they did not contain any free sulphuric acid revealed by using methyl orange.

The first series of experiments was made by adding 10 per cent. of sulphuric acid, this addition having for object the prevention of the formation of basic salts. Under these conditions the observed increase of weight of the large cathode was always considerably less than in the case of the small one. The following are the figures:—·1903 grm. and ·1960 grm. If the cathodes were left in the solution for a period equal to that during which the current passed, they lost respectively 9·2 and 3·2 milligrammes. If these numbers are added to the first we get ·1995 grm. and ·1992 grm., which shows that we may attribute the discrepancy to the dissolving away of the deposited copper.

It only remained to discover the way in which this disturbing action could be suppressed. This object was not attained either by leaving copper turnings for a long time in the solutions, or by trying to neutralise the acid by means of copper hydride carefully washed and dried. Finally, it was observed that by dissolving pure sulphate of copper, twice crystallised, a liquor was obtained in which a sheet of copper increased in weight (the increase was probably due to the brown layer which formed on the plate). It was then only necessary to mix this solution with another containing 1 per cent. of sulphuric acid, in the proportion of 1 litre of the first to ·59 of the second, to obtain a liquid which had no dissolving action on copper; this liquid also was neutral. The experiment of placing the sulphate of copper voltameters in series with one containing nitrate of silver was then carried out in order to determine the ratio of the electro-chemical equivalents of the two metals.

* *Wied. Ann.* Translated from *La Lumière Électrique.*
† *Phil. Mag.*, Vol. XXII., p. 389, Vol. XXV., p. 179.

The following table gives the results of six experiments:—

	Duration of experiment in hours.	Average current amperes.	Weight of copper deposited. Large plate.	Small plate.	Mean.	Weight of silver deposited.	Ratio.	Electro-chemical equivalent of copper.
1	1	·292	·3447	·3449	·3448	1·1740	·2937	3.284×10^{-7}
2	2	·228	·5396	·5397	·5397	1·8360	·2936	3.283
3	2	·221	·5228	·5232	·5230	1·7802	·2938	3.285
4	2	·150	·3535	·3531	·3533	1·2021	·2939	3.286
5	1	·230	·2717	·2714	·2716	·9251	·2936	3.282
6	1	·245	·2904	·2900	·2902	·9870	·2940	3.287
							·2938	3.284×10^{-7}

It will be seen that the numbers in the third and fourth columns never differ from each other by as much as five units in the fourth place of decimals, in other words they are equal within the limits of experimental error. The figures in the last column have been calculated by assuming the electro-chemical equivalent of silver to be ·001118. If we take the values of the equivalents given in the tables of Landolt and Boernstein, *i.e.* 31·59 and 117·66, their ratio is ·2934, and the electro-chemical equivalent of copper is $3{,}281 \times 10^{-7}$. It is to be observed that the equivalent of copper is known to within ·25 per cent., and that of silver to within ·05 per cent., so that their ratio is only known to within ·8 per cent. The discrepancy between the value of the ratio as given by these tables and that determined by the author is less than this. The agreement is, therefore, satisfactory.

It was assumed in the first series of experiments that the dissolving action of the solution remained the same when no current was passing. The results of the second series, in which the dissolving action was suppressed, justify this supposition.

THE ELECTRIC LIGHT IN LIGHTHOUSES.*

It would seem proper that the adoption of an improvement should be influenced above all things by the degree of appreciation of it which is felt by those who will be called on to make use of it; since, whether an improvement is really such often depends upon circumstances of which practical men are the best judges. This is indeed only common sense, but it is not governmental. What *is* governmental is to adopt an improvement everywhere simply because it is one somewhere. Thus the electric light possesses valuable qualities, and its numerous advantages will increase as it is perfected; it is an improvement.

Now, the Government, persuaded by an inventor, thought it would be an advantage to apply this improvement to lighthouses; and the authorities were not mistaken. What the Government did make a mistake about was the degree of efficacy and utility of this light for this special purpose. It was decided to inaugurate this reform at the two lighthouses of La Hêve (near Havre), only one of them being at first fitted with the electric light.

The mariners who frequented these parts soon discovered that if the electric light was superior to the oil light in clear weather, it was less and less penetrating and even became invisible in foggy weather; while the latter, losing considerably less, remained visible much longer. This was an experimental proof that the fog-penetrating power of the electric light was notably less than that of an oil light. The reason for this was given, if we remember rightly, some ten years ago by a clever engineer in the lighthouse service, M. Lucas, and we mentioned the matter at the time. We regret to say that we have mislaid M. Lucas's paper.

In a private concern, such a statement duly verified would condemn a system, since granting the ingenuity of a system its efficacy would have to be superior to that of a commonplace method. But the utility of lighthouses increasing with the density of a fog, it is doubly absurd to retain a method of lighting the efficacy of which increases with the clearness of the atmosphere, but diminishes and becomes zero much more

* From the *Moniteur Industriel.*

Digitized by Google

rapidly than that of the older system at the very moment when the light is most wanted. But Government, once set in motion, does not stop for such a trifle. The electric light already installed in the chief lighthouses will soon be found in all. Let the sailors get out of the difficulty as best they can! and are they not satisfied at being in the right when science is in the wrong? There being moreover a spirit of emulation between country and country, and Governments being much the same everywhere, electricity has taken or is about to take the place of oil on most coasts. England, whose *amour-propre* often obscures its practical way of looking at things, has made the same mistake.

According, however, to a contemporary the English Association of Master Mariners has lodged complaints at Trinity House with regard to the insufficiency of the electric light in lighthouses, and the various inconveniences which it presents to navigators. They allege that they have often had occasion to observe at the mouth of the Thames the inefficacy and low power of the electric lights, which are often invisible under certain atmospheric conditions, whilst the oil lights of the lightships or the gas lamps of the seaside towns are perfectly visible. Moreover, the glare of a powerful light, such as the one at South Foreland, inconveniences ships in its vicinity in another way: it dazzles the navigators, who are, therefore, unable to keep a proper look out, and the intensity of the rays projects the shadows of hulls and rigging to a great distance, forming regular phantom ships and rendering it difficult to judge distances on a dark night.

We may be sure that the voice of the English mariners will be heard and taken notice of. England will not be deterred by the question of expense from giving satisfaction to the shipping interest, and adding to the security of her coasts; and if it is found necessary to increase the intensity of the lights in order to augment their range in bad weather, this difficulty will not cause her to draw back.

It would be a good thing if the same course were taken on all foggy coasts, and if the electric light were reserved only for those coasts where fogs are the exception. But we must not expect it, the Government must not stultify itself.

Let us take this opportunity of correcting an error into which people too often fall. What is wanted of a lighthouse is not that it shall *illuminate* the path of a ship, but that it shall furnish a luminous point; not that it shall show one where one is going to, but indicate to the mariner where he is and whither he should go. Lights are recognised by their colours, fixity, alternations of colours, durations of flashes. By these means a sailor discovers his whereabouts, and he is hampered rather than aided by a flood of light. It is, therefore, a mistake to choose the electric light for lighthouses because it affords the most powerful illumination. This, also, mariners would have told the Government if it had deigned to consult them.

ON THE DISCHARGE OF ELECTRICITY THROUGH EXHAUSTED TUBES WITHOUT ELECTRODES.*

BY J. J. THOMSON, M.A., F.R.S.

The following experiments, of which a short account was read before the Cambridge Philosophical Society last February, were originally undertaken to investigate the phenomena attending the discharge of electricity through gases when the conditions are simplified by confining the discharge throughout the whole of its course to the gas, instead of, as in ordinary discharge tubes, making it pass from metallic or glass electrodes into the gas, and then out again from the gas into the electrodes.

In order to get a closed discharge of this kind we must produce a finite electromotive force round a closed circuit, and since we cannot do this by the forces arising from a distribution of electricity at rest, we must make use of the electromotive forces produced by induction. To break down the electric strength of the gas such forces must be very intense while they last, though they need not last for more than a short time. Forces satisfying these conditions occur in the neighbourhood of a wire through which a Leyden jar is discharged. During the short time during which the oscillations of the jar are maintained enormous currents pass through the wire, and as with a moderate sized jar these currents change their direction millions of times in a second, the electromotive force in the neighbourhood of the wire is exceedingly large. To make these forces available for producing an electrodeless discharge, all we have to do is to make the wire connecting the coatings of the jar the primary of an induction coil of which the discharge tube itself forms the secondary. The arrangements which I have employed for this purpose are represented in the accompanying diagram.

In (α) A is the inside coating of a Leyden jar; this is connected to E, one of the poles of a Wimshurst electrical machine, or an induction coil, the other pole F of the machine being connected to B the outer coating, of the jar. A C D is a wire connected to the inner coating of the jar, a few turns C (which we shall call the primary coil) are made in this wire; these turns are square if the discharge tube is square, circular if the discharge tube is a spherical bulb. The wire at D is attached to an air break, the other side of which is connected with the outer coating of the Leyden jar. The knobs of this air break ought to be kept brightly polished. The loop C is connected to earth. The discharge tubes, which were in general either rectangular tubes or spherical bulbs, were placed close to the turns of C. When the difference of potential between A and B is sufficiently large, a spark passes across the air break, and the electrical oscillations set up produce a large electromotive force in the neighbourhood of the coil, sufficient under favourable circumstances to cause a bright discharge to pass through the vacuum tubes. In some experiments the jars, at the suggestion of Professor Oliver Lodge, were connected up differently, and are represented by (β) in Fig. 1. Two jars were used, the outside coatings of which, A and B, were connected by the wire containing the primary coil C, the inside coating of the first jar was connected to one pole of the Wimshurst, that of the second to the other. With this method of arranging the jars no air space is required, as the sparks pass between the terminals of the machine, and the polishing of these terminals is not nearly so important as that of the knobs of the air break in the arrangement (α).

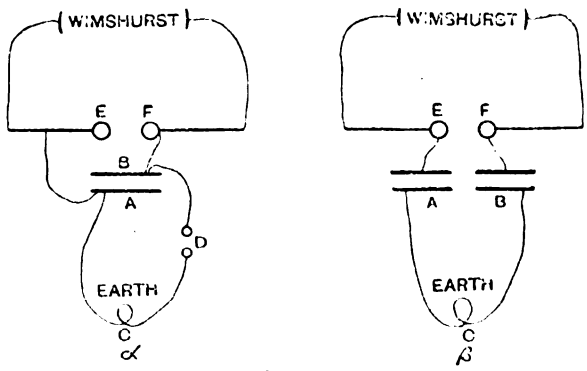


FIG. 1.

Before proceeding to describe the appearance presented by the discharge, I will mention one or two points which may prove useful to any one who wishes to repeat the experiments. According to my experience the discharge is more easily obtained in bulbs than in square tubes, and with a Wimshurst machine than with an induction coil. If an induction coil is used a break which will transmit a large current ought to be substituted for the ordinary vibrating one supplied with such instruments. It is essential to success that the gas in the bulbs or tubes should be quite dry and at a suitable pressure; there is a pressure at which the brilliancy of the discharge is a maximum, and as in endeavouring to get at this pressure the exhaustion may be carried too far, it is convenient to use a form of mercury pump which will allow of the easy admission of a little gas; the pattern which I have used and found to answer very well is called the Lane-Fox pattern. When any gas is introduced it should be sent through sulphuric acid to get rid of any moisture that may be in it. Owing, I think, to the pressure in ordinary incandescent lamps being very different from that at which the discharge has its maximum brilliancy, I have met with very poor success in attempts to produce these discharges in already exhausted tubes such as incandescent lamps, though I have tried a considerable number by different makers; on the other hand, the radiometers which I have tried allow the discharge to pass pretty readily, though it is interfered with by the vanes, and is not comparable in brilliancy with that obtained in home-made tubes and bulbs. I have obtained sparks easily with apparatus of the following dimensions:—two gallon jars, the outside coatings connected by a wire about two yards long, the coil consisting of three or four turns, each about 3in. in diameter. I have some bulbs which with this apparatus will give a bright discharge when the distance between the terminals of the Wimshurst is only $\frac{1}{4}$in.; these are,

* Abstract from the *Phil. Mag.*, October, 1891.

Digitized by Google

however, exceptionally good; it more frequently takes a spark an inch or an inch and a half long to produce the discharge.

I find that Hittorf in Wiedemann's *Annalen*, XXI., p. 138, describes the light produced in a tube round which the wire connecting the coatings of a Leyden jar is twisted; the luminosity in Hittorf's experiments seems to have filled the tube, and not, as in the experiments described in this Paper, been confined to a ring. It seems possible that the difference in the appearance in the tubes may have been due to the existence of an electrostatic action in Hittorf's experiments, the primary coil getting raised to a high potential before the discharge of the jar, and inducing a distribution of electricity over the inside of the glass of the tube; on the passage of the spark the potential of the primary coil will fall, and the electricity on the glass redistribute itself; to effect this redistribution it may pass through the rarefied gas in the discharge tube and produce luminosity.

In my experiments I took two precautions against this effect; in the first place I connected the primary coil to earth, so that its potential before discharge took place was unaltered, and as an additional precaution I separated the discharge tube from the primary by a cage made of blotting paper moistened with dilute acid; the wet blotting paper is a sufficiently good conductor to screen off any purely electrostatic effects, but not a good enough one to interfere to an appreciable extent with the electromotive forces arising from rapidly alternating currents. In this way we can screen off any electrostatic effects due to causes which operate before the electrical oscillations in the jars begin; when once these have commenced, there ought not, I think, to be any separation of the electromotive forces into two parts, one being called electrostatic, the other electrodynamic. As this is a point on which it is desirable to avoid any misunderstanding, I hope to be excused if I treat it at some length. (The author then discusses the mathematical treatment of the phenomena of the "Electro-magnetic Field.")

We may thus regard the distinction between electrostatic and electro-magnetic electromotive forces as one introduced for convenience of analysis rather than as having any physical reality. The only difference which I think could be made from a physical point

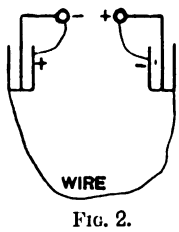

Fig. 2.

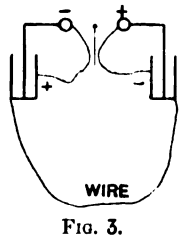

Fig. 3.

of view would be to define those effects as electrostatic which are due to tubes of electrostatic induction having free ends, and to confine the term electro-magnetic to the effects produced by closed endless tubes. It is only, however, when the electromotive forces are produced exclusively by the motion of magnets that all the tubes are closed; whenever batteries or condensers are used, open tubes are present in the field.

It will be useful to consider here the disposition and motion of the tubes of electrostatic induction in the arrangement used to produce these electrodeless discharges. We shall take the case where two jars are used, as in β (Fig. 1), as being the more symmetrical.

Just before the discharge of the jar, the tubes of electrostatic induction will be arranged somewhat as follows:—There will be some tubes stretching from one terminal of the electric machine to the other; others will go from the terminals to neighbouring conductors, the table on which the machine is placed, the floor and walls of the room, &c. The great majority of the tubes will, however, be short tubes passing through the glass between the coatings of the jars. Let us now consider the behaviour of two of these tubes, one from the jar A, the other from B, when a spark passes between the terminals of the machine. Whilst the spark is passing these may be regarded as connected by a conductor; the tubes which originally stretched between them now contract, the repulsion they exerted on the surrounding tubes is destroyed so that these now crowd into the space between the terminals, the two short tubes under consideration now taking somewhat the form shown in Fig. 2. These tubes being of opposite sign tend to run together; they do so until they meet as in Fig. 3, when the tubes break up as in Fig. 4, the upper portion running into the spark-gap, where it contracts, while the lower portion rushes through the dielectric to discharge itself into the wire connecting the coatings of the jars, an intermediate position being shown in Fig. 5. These tubes while rushing through the dielectric produce, as already stated, magnetic forces; some of them on their way to the discharging wire will pass through the discharge-tube; if they congregate there in sufficient density, discharge will take place through the rarefied gas.

The discharge of the jar is oscillatory, and we have only followed the motion of the tubes during a part of the oscillation; when, however, this tube enters the wire between the jars a tube of opposite kind emerges from it; the same thing happens when the other portion enters the spark-gap. These go through the same processes as the tubes we have followed, but in the reverse order, until we get again two short tubes in the jars, but opposite in sign to the original ones; the process is then repeated and so on as long as the vibrations last.

In order to see what are the most advantageous dimensions to give to our apparatus, let us consider on what the maximum electro-motive force in the secondary depends. Let us take the case of a condenser of capacity C discharging through a circuit whose coefficient of self-induction is L; then, if the potential difference between the plates of the condenser is initially V_0, the current γ at the time t is (supposing as a very rough approximation that there is no decay in the vibrations) given by the equations

$$\gamma = \frac{C V_0}{\sqrt{LC}} \sin \frac{t}{\sqrt{LC}}.$$

The rate of variation of this, $\dot{\gamma}$, is therefore

$$\frac{V_0}{L} \cos \frac{t}{\sqrt{LC}}.$$

So that if M is the coefficient of self-induction between the primary and a secondary circuit, the maximum electromotive force round the secondary is $M V_0 / L$, which for a given spark-length is independent of the capacity of the condenser. In practice it is advisable, however, to have as much energy in the jars to start with as possible, and better results are got with large jars than with small ones. Using a six-plate Wimshurst machine I got very good results with two "gallon jars;" with a large induction-coil the best results were got with two "pint and a-half jars."

The best number of turns to use in the primary coil C depends upon the size of the leads; if all the circuit were available for this coil one turn would give the largest electromotive force,

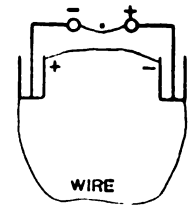

Fig. 4.

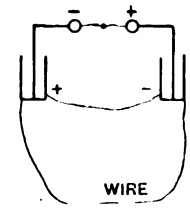

Fig. 5.

because though for a given rate of change of the current in the primary the effect on the secondary increases with the number of turns, the rate of change of the current varies inversely as the self-induction of the primary, so that if all the circuit is in the coil C, since an increase in the number of turns will increase the self-induction of the circuit faster than the mutual induction, it will diminish the electromotive force round the secondary. In practice, however, it is not possible to have the whole of the wire connecting the coatings of the jar in the coil C; and in this case an increase in the number of turns may increase the mutual induction more than the self-induction, and so be advantageous. The best result will be obtained when the self-induction in the coil C is equal to that of the remainder of the circuit. It is very easy to find by actual trial whether the addition of an extra turn of wire is beneficial or the reverse. The brightness of the discharge depends upon the time of the electrical oscillations as well as upon the magnitude of the electromotive force. Thus, in an experiment to be described later, the brilliancy of the discharge was increased by putting self-induction in the leads which, though it diminished the intensity of the electromotive force, increased the time-constant of the system. When the discharge-tube was square, and the coil C had also to be square, it was found most convenient to make it of glass tubing bent into the required form, and filled with mercury. When, however, the discharge was required in a bulb, the primary coil was made of thick gutta-percha-covered copper wire wound round a beaker just large enough to receive the exhausted bulb. There is sometimes considerable difficulty in getting the first discharge to pass through the bulb, though when it has once been started other discharges follow with much less difficulty. The same effect occurs with ordinary sparks. It seems to be due to the splitting up of the molecules by the first discharge; some of the atoms are left uncombined, and so ready to conduct the discharge, or else when they recombine they form compounds of smaller electric strength than the original gas. When the discharge was loath to start, I found the most effectual way of inducing it to do so was to pull the terminals of the Wimshurst far apart, and then, after the jars had got fully charged, to

Digitized by Google

push the terminals suddenly together. In this way a long spark is obtained, which, if the pressure of the gas is such that any discharge is possible, with the means at our disposal, will generally start the discharge.

Appearance of the Discharge.

Let us suppose that we have either a square tube placed outside a square primary or a bulb placed inside a circular coil of wire, and that we gradually exhaust the discharge-tube, the jars sparking all the time. At first nothing at all is to be seen in the secondary, but when the exhaustion has proceeded until the pressure has fallen to a millimetre or thereabouts, a thin thread of reddish light is seen to go round the tube situated near to but not touching the side of the tube turned towards the primary. As the exhaustion proceeds still further, the brightness of this thread rapidly increases, as well as its thickness ; it also changes its colour, losing its red tinge and becoming white. On continuing the exhaustion the luminosity attains a maximum, and the discharge passes as an exceedingly bright and well-defined ring. On continuing the exhaustion, the luminosity begins to diminish until, when an exceedingly good vacuum is reached, no discharge at all passes. The pressure at which the luminosity is a maximum is very much less than that at which the electric strength of the gas is a minimum in a tube provided with electrodes and comparable in size to the bulb. The pressure at which the discharge stops is exceedingly low, and it requires long-continued pumping to reach this stage. We see from these results that the difficulty which is experienced in getting the discharge to pass through an ordinary vacuum-tube when the pressure is very low is not altogether due to the difficulty of getting the electricity from the electrodes into the gas, but that it also occurs in tubes without electrodes, though in this case the critical pressure is very much lower than when there are electrodes. In other words, we see that as the state of the bulb approaches that of a perfect vacuum its insulating power becomes stronger and stronger. This result is confirmed by several other experiments of a different kind, which will be described later.

The discharge presents a perfectly continuous appearance, with no sign of striation, of which I have never observed any trace on any of these discharges, though I must have observed many thousands of them under widely different conditions.

(To be continued.)

EXPERIMENTS WITH HIGH-TENSION CURRENTS.*

It is almost impossible to convey by words any idea of the visible phenomena accompanying the efforts of a 40,000 volt current to bridge an open space, but we will attempt a description of what we saw one evening last week. Upon a table there was fixed an electrode, some 3in. in diameter, connected to one terminal of a transformer. Over it there was mounted a large sheet of glass 3 millimetres thick, and above the glass there was a second electrode terminating in a sharp point, the distance between the electrodes being 3 centimetres. When the current was turned on to the primary coil of the transformer there first appeared a purple haze at the upper electrode, streaming towards the glass ; as the current increased this haze grew in fulness and definition, and began to throw out feelers which darted outwards, and as quickly withdrew. As the electromotive force augmented still further these feelers gathered power until they beat themselves violently on the glass, as if they would force themselves through it in their mad desire to reach the other electrode. The whole space below the pointed conductor became alive with them, and exhibited a mass of leaping, crackling threads of purple fire, which writhed and twisted in impotent attempts to burst through the barrier, and failing that, spread themselves along its surface endeavouring to rush over its edges, and so reach their goal by a circuitous route. But this was beyond their strength until the electromotive force approached 45,000 volts, when suddenly the entire appearance was changed. The current overleapt the edges of the plate and flowed completely round it in all directions. At that moment the intense purple colour of the spark disappeared, and was replaced by white light of the greatest brilliancy, which surged and scintillated in a way that produced acute fatigue of the eyes in an extraordinarily short time. Although steadier than before, the discharge still kept up its spark-like character, enfolding the glass plate in gleaming coruscations, which glistened and flashed until the spectators were fain to turn away their bedazzled gaze.

A change in the arrangement was then made. The upper pointed electrode was replaced by a brass disc 3in. in diameter. This was laid over the surface of the glass plate with three very thin washers of vulcanite intervening between the two. The current was then turned on, in the same gradual manner as before. The space between the two discs immediately filled with purple light, which had sufficient motion in it to recall the flame of a Bunsen burner, spread out under the bottom of a beaker. Sparks then began to appear at the edges, and, as they gathered strength, to radiate a little beyond them. Gradually they became streamers stretching out along the surface of the plate, in curved fanciful forms, which twined and twisted and weaved themselves into a glistening filagree, compared by an imaginative spectator to an agonised Japanese chrysanthemum. This experiment had not the brilliant refulgence of the one that preceded it, but was characterised by a quivering irradiation which writhed and tossed like a bird beating itself at the bars of its cage. In spite of its less formidable appearance, however, it proved destructive to the glass, which presently flew in pieces with a crash. Several sheets were tried in succession, but each was pierced and broken, and allowed the current to attain its object of flowing directly from one electrode to the other.

The last demonstration showed an arc under a pressure of 44,000 volts. When the electrodes approached to within 5in. the arc established itself, but instead of the flames bridging the space they streamed out in two thin tongues at right angles to the electrodes, and parallel to each other. If the electrodes were pushed nearer together the flames deserted their extremities and wandered back along their stems, evidently repelling each other. The light produced was, of course, very small indeed.

In conclusion, we may add that the voltage was reached by two transformations. An 80-volt current was first raised to 2,000 volts by one of Siemens' cable transformers, consisting of a long core of wire rope, composed of soft iron wires covered with a layer of specially prepared insulating material, around which are wound two insulated conductors, forming one the primary and the other the secondary circuit of the transformer. The secondary current was then raised to 45,000 volts by a transformer of the usual type.

* From *Engineering*, October 30, 1891.

LEGAL INTELLIGENCE.

Muirhead v. the Debenture Guarantee and Investment Company (Limited).

The plaintiff in this action, which came before Mr. Justice Denman and a Special Jury in the Queen's Bench Division on Wednesday last, alleged that in April, 1889, he introduced to the defendants certain business with the St. James's and Pall Mall Electric Lighting Company, who required capital for the extension of their operations. The plaintiff sued for commission upon these transactions, and the defendants denied their liability, alleging that the business did not come to them through the instrumentality of the plaintiff. Some evidence having been given, an arrangement was come to, and there was judgment for the plaintiff for £1,200, but without costs.

CORRESPONDENCE.

THEORY OF THE WIMSHURST MACHINE.

TO THE EDITOR OF THE ELECTRICIAN.

Monsieur : En réponse à votre note (p. 599) : "The theory of M. Pellissier is very similar to that given by Prof. Thompson," voici en quoi, surtout, cette théorie diffère de celle que j'ai présentée :

M. Thompson suppose que si A_1 (voyez le schema, p. 604) est (+), par son influence B_1 deviendra (−) A B_5 (+) ; cela ne peut être puisque $\beta\beta_1$ n'est pas isolé ; B_1 seul s'électrise ; la charge de B_5 provient d'une autre cause.

La théorie du savant professeur n'explique donc pas la distribution de l'électricité sur les plateaux ; c'est pourtant le point capital puisque l'accroissement des charges en est le résultat.

Agréez, Monsieur, l'assurance de mes sentiments très distingués,

Paris, 31 Octobre, 1891. G. Pellissier.

[We give the remarks of our esteemed correspondent in his own words, as we do not consider that the fact to which he alludes is inconsistent with the criticism we made. Whether $\beta\beta_1$ is insulated or not, any theory which accounts for the negative charge on B_1 will also account for the positive charge of B_5. We, however, agree that M. Pellissier's explanation of the growth of the charge is novel.—Ed. *E.*]

TO THE EDITOR OF THE ELECTRICIAN.

Sir : In reply to M. Pellissier, it seems to me that the growth of the charges is explained very well according to my

Digitized by Google

theory without the intervention of the conductor $\beta\beta_1$; since the lower half of the machine is only a reduplication (with a change of signs) of the upper half. Each half can charge itself.—I am, &c., SILVANUS P. THOMPSON.

London, November 4, 1891.

ACCIDENT AT CHELMSFORD.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The accident which recently occurred at Chelmsford, and which has been somewhat widely reported, is interesting in one respect that it shows that the use of overhead wires may in some cases increase the safety of the public instead of being dangerous, as has been so often stated by their opponents. A runaway omnibus passing through the narrow street which leads to the station came in contact with one of our arc lamp-posts with such violence as to break off an exceedingly massive casting at the ground line. If the wires had been underground the pole would have fallen into the street and probably caused serious damage. As it was, although broken short off, it was held upright by the system of overhead conductors attached to it, and no damage was done to anything but the arc lamp itself.—We are, &c.,

CROMPTON & Co.

Mansion House Buildings, London, E.C.,
November 2, 1891.

SAX'S COMMUNICATOR FOR CARRIAGES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your notice *re* my patent communicator for carriages, cabs, &c., in your current issue you state, "the accumulators used last for about 15 hours," without further mentioning the electric light fitted in the same vehicles, so that that remark would appear to refer to the indicators, which of course is not the case.

Could you kindly correct this in the next number?—I am, Sir, &c., JULIUS SAX.

7, Ridgmount-street, Store-street, London, W.C.,
November 3, 1891.

CLOSED CONDUITS FOR ELECTRIC TRACTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of October 30th you publish a letter in which the writer makes a general claim to the invention of closed conduits for electric tramways some eight years ago, and you add an editorial note calculated to convey the impression that the whole ground had been covered previously by yet another inventor. A similar claim having been made by others in the daily press I felt called upon to address a few words in reply; and as my letter, which appeared in the daily press this week, is equally applicable as an answer to your correspondent, I trust you will kindly insert the same in your next issue.—I am, Sir, &c., JOHN GORDON.

The Gordon Electric Traction Syndicate (Limited),
49, Greenwich-road, S.E., Nov. 3, 1891.

SIR: In a recent issue of your journal Messrs. Foote and von Buch address a letter to you in which they assert, without adducing a single iota of evidence, that "the principle of my method of supplying electricity to tramway rails was protected by several English inventors long before Mr. Gordon," and single out Mr. Lineff, Mr. Wynne, and Messrs. Ayrton and Perry.

It is with considerable reluctance that I beg to trespass upon your valuable space, as the readers of a daily journal are not the judges who have to decide a question of priority of invention. On the other hand, as the public desirous of investing capital in any promising scheme are apt to be misled and their minds unsettled by such unwarrantable statements as those contained in the letter above referred to, I think that I owe it to myself and my supporters to contradict these statements.

In the first place a "principle" cannot be protected by patent law. Mr. Lineff and myself, in common with everyone else who has given attention to the closed-conduit systems, use an interrupted surface conductor as the medium through which the current is conveyed from the main conductor to the motor on the car. But here the resemblance between the two systems ends. The means by which the desired object is accomplished are totally different, and I am certain that Mr. Lineff himself would be the last to assert that my system resembled or infringed his.

The Wynne system involves electro-magnetic mechanisms, placed in water-tight boxes under the roadway, *every eight or nine feet* or so, and the employment of the main current for operating these mechanisms; whereas two of the main features of the Gordon system are the absence of moving parts and mechanism under the roadway and the employment of a shunt current only for working the electro-magnetic distributors, which put the sections of the interrupted conductor into and out of connection with the main conductor. These are placed under the pavement about *100 yards apart* in such a way that they can be readily examined, tested, and, when necessary, repaired, without interference with the traffic or disturbing the roadway communication between these and the various sections of the divided centre rail is effected by means of service conductors, one for each section.

Without wishing in the slightest degree to detract from the praises due to Messrs. Ayrton and Perry, "whose names have been," as mentioned in Messrs. Foote and von Buch's letter, "so honourably connected with the very earliest endeavours to apply electricity to the propulsion of railways and tramways," I would beg to submit that the fact that after the lapse of ten years the invention for the propulsion of tramcars on an ordinary thoroughfare claimed for Messrs. Ayrton and Perry has got no further than the paper stage, is *primâ facie* evidence that the special system referred to is impracticable. It is one thing to describe a beautiful and ingenious system in a patent specification, but it is another thing to describe and protect a system and then work out that system practically according to that description. The time since we began to put the Gordon system to a practical test must be counted by months instead of years. A full-gauge line, 70 yards long, has been constructed at the works of Messrs. Merryweather and Sons, fire engine and tramway engineers, Greenwich, and the results have been so favourable that already negotiations are on foot for the construction of a line of considerable mileage on the Gordon system.

With regard to the reported wonderful invention of Mr. Edison for tramcar propulsion, I think that the article published in the *Daily Oracle* for October 24th, and my letter addressed to and published in the same organ for October 29th, as well as the comments of the technical press, will set at rest the minds of those who have been agitated by this American "boom." Trusting that the daily growing interest in this subject will be sufficient excuse for trespassing so much on your valuable space,—I am, &c.,

The Gordon Electric Traction Syndicate (Limited), JOHN GORDON.
49, Greenwich-road, S.E.

[Mr. Gordon's idea was described in *The Electrician*, Vol. XXVII., p. 281. The length of the conductors is about seven times that of the track, and it is proposed to use 7/18s. The inventor's estimate for adapting an existing tramway to his system is about £2,000 per mile. More details may be found in the patent specification, No. 6,083, 1890 (price 1s. 1d.). No subsequent improvement appears to have been patented. Profs. Ayrton and Perry proposed to place one magnet at a time under the lines; and Mr. Wynne suggested putting them in boxes sunk alongside the track, if necessary under the pavement, Mr. Gordon groups twenty or thirty together in one box. He first describes an arrangement with a rotating switch-arm pulled round by a number of successive magnets; but towards the end of the final specification he makes this rather amusing statement, "As the result of recent experiments (and having regard to the obligation imposed upon me to disclose the best means with which I am acquainted for carrying out my invention) I prefer to arrange the distributing apparatus in such a manner that the centrally pivoted revolving arm previously described may be dispensed with." He then describes the use of ordinary magnets for the same purpose. We cannot see the advantage of continuing a discussion on a system which has only been tried on 70 yards in the maker's works, but shall be glad to describe it fully after a few miles of line have been in public operation for a few months.—ED. *E.*]

HARTMANN AND BRAUN INSTRUMENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We are much obliged to you for the care and attention you have given our instruments in the current number of your esteemed paper, on pages 705, 711, 717, and 718; and we take this opportunity to ask you to be good enough to give us space for making some small corrections. Fig. 1 is an ordinary Kohlrausch ampere-meter *without* mercury. Fig. 2 your type-setter has placed upside down. German scientific instruments are by no means in an undeveloped condition, as you remark. Numbers of your readers who saw Hartmann and Braun's pavilion at the Frankfort Exhibition will hardly have come away with that impression. The clock shape has long ago gained pre-eminence in Germany, as it has in England. We should also like to point out that Fig. 3, which

Digitized by Google

HARTMANN AND BRAUN'S INSTRUMENTS.

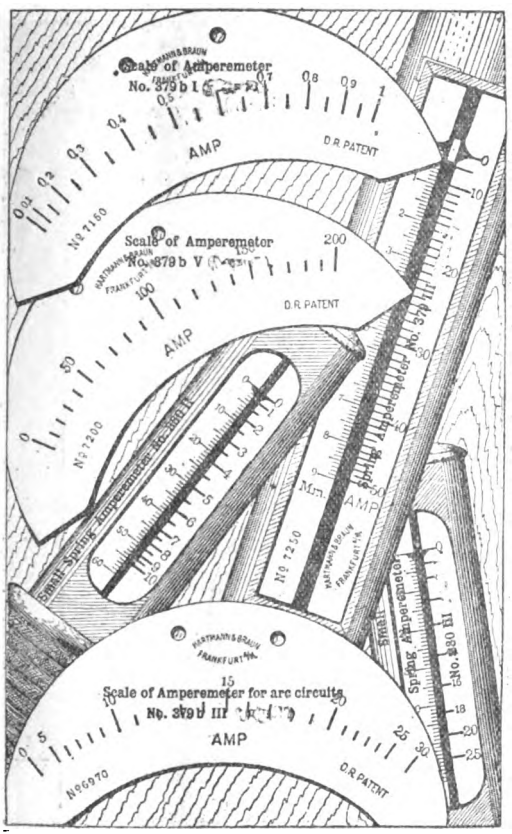

Diagram of Ampere-meter Scales (half full size).

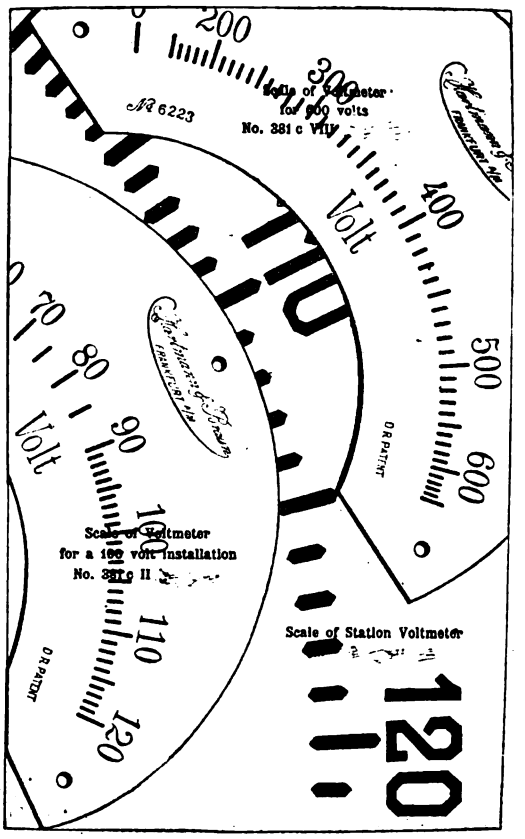

Diagram of Voltmeter Scales (half full size).

represents any instrument which may have been ready at the time when the wood engraver was called in, by no means infers that these instruments can only be made like this sketch, with—as you say—a non-uniform scale. It is the fact that by our being able to produce any scale we may be asked for, either uniform throughout or uniform in any part, or in wide readings at any given point, that our instruments (volt and ampere-meters) find such universal favour, and are so largely in use in England as well as elsewhere. Allow us to hand you herewith reduced illustrations of some of our volt and ampere-meter scales, which will at once convince you that the adaptability of our construction of instruments to anything we are asked for is our great point, apart from the accuracy everyone expects and finds in high-class German scientific instruments.—We are, Sir, &c.,

HARTMANN AND BRAUN.
London Office: O. Berend and Co.

[This matter is referred to in our Editorial columns.—ED. *E.*]

THE NEW GERMAN PATENT LAW.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It will be of interest to your readers to know that a new Patent Law has recently (October 1, 1891) come into force in Germany, whereby important changes of considerable importance to inventors are effected.

According to the provisions of the present law, an invention is considered new if at the date of filing the application for patent it has not been so described in public prints within the last century, or so publicly employed in the German Empire that the use of the same by persons skilled in the art appears possible. The official foreign patent specifications are only considered equal to public prints after the lapse of three months from the date of publication, in so far as the patent is applied for by the foreign patentee or his legal successor. This exception only refers to the official publications of those States in which (according to an official publication) reciprocity is guaranteed.

It will be remembered that hitherto an invention was not considered new in Germany if it had been already described in any printed publication whatever, or publicly used in Germany at the date of the application for patent. Also, if a patent is granted for a process, its scope is extended to the direct products of the process. A very much more complete and satisfactory system of examination of applications is provided, a permanent staff being appointed, and each examiner is confined to his own department; further, it is enacted that where an applicant appeals from the decisions of the application or annulment departments, no member who took part in the decision appealed against may take part in the decision on such appeal.

This is certainly a step in the right direction, and it appears probable that the final decisions will, at any rate, be less unfair than hitherto under the old system of non-permanent or "casual" examiners, who reconsidered their own decisions on appeal with an obvious result.

Another new departure is a "Law for the Protection of Useful Models." It is a most important supplement to the new Patent Law, which latter it in some respects supersedes.

All kinds of tools and implements which cannot be patented can be protected by this law—even the subjects of refused patent applications can now in many cases be protected. A most important provision is that applications are accepted without examination. The protection lasts six years, and promises to prove of value for all kinds of small inventions not perhaps worth patenting fully.—I am, &c.,

J. C. CHAPMAN (Chartered Patent Agent).

70, Chancery-lane, London, W.C.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—An extraordinary general meeting of this Company was held yesterday (Thursday) at Winchester House, Sir David Salomons, Bart., in the chair. The following resolution was carried unanimously:—"*That the special resolution which was passed at the ordinary general meeting of the Company, held on the 15th day of October, 1891, as follows:—That Article No. 13 of the Company's Articles of Association be altered by inserting after the words 'each call' at the end of the fourth line, the following:—'and that no call shall exceed one-fifth of the nominal amount of a share, or be made payable within two months after the last preceding call was payable,' be and is hereby confirmed.* A fuller account of this meeting will appear in our next issue.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

NOW READY.—"THE ELECTRICIAN" PRIMERS (38 in all. Vol. I., 20; Vol. II., 18), in two volumes. Price per volume 2s. paper covers, 2s. 6d. cloth; post free, 2s. 2d. and 2s. 9d. respectively. Single copies, 3d.; post free, 3½d. Prospectus on application to the Publisher.

TENDERS INVITED.—The Midland Railway Company desire tenders for the supply of general stores, including (No. 10) telegraph instruments, wire, &c. Forms of tender may be obtained of Mr. Pettifor, General Stores Department, Derby; and tenders are to reach the Secretary of the General Stores Committee, Midland Railway, Derby, by 9 a.m. on November 11th.

——— The Cheshire Lines Committee are prepared to receive tenders for the supply, during the year 1892, of stores and material, including (No. 7) telegraph materials, instruments, wire, &c. Specifications and forms of tender may be obtained from Mr. S. S. Barton, storekeeper, Cheshire Lines, Warrington; and tenders are to reach Mr. Edward Ross, secretary, London-road Station, Manchester, by 10 a.m. on November 28th.

TENDERS ACCEPTED.—The tender of the Jensen Electric Bell and Signal Company (Woodhouse and Rawson United, Limited) has been accepted by the Metropolitan Asylums Board for the maintenance in proper working order of the electrical apparatus at the Darenth Asylum and Schools, at £75 per annum.

——— The Southampton Harbour Board have accepted the tender of Mr. F. Shalders, High-street, Southampton, for supplying electric light fittings for the pier, for £575.

BRUSSELS.—The following contractors have sent in tenders for the general electric lighting plant of Brussels:—S. Z. de Ferranti (Limited), London; Crompton and Co., London; Schückert and Co., Nuremburg; Siemens and Halske, Berlin; India Rubber Company, London; Compagnie Internationale d'Electricité, Liège.

SALES BY AUCTION.—We refer our readers to our advertisement columns for particulars of sales by auction by Messrs. Wheatley Kirk, Price and Goulty, at 39, Queen-street, London, E.C., on Wednesday, the 11th inst., and following days; and at the Star Tube Works, Heneage-street, Birmingham, on Tuesday, the 17th inst., and following days.

THE FORTHCOMING ELECTRICAL EXHIBITION AT ST. PETERSBURG.—The following notice was given by the *Russkiya Viedomosty* on the 7th (19th) October last:—"Seventy foreign exhibitors have consented to participate in the next Electrical Exhibition at St. Petersburg. Mr. Edison has paid 2,000 roubles (£200) for the space which he intends to occupy at the Exhibition. Among his new inventions prominence will be given to an electrical fountain and lighthouse. The German branch of the Thomson-Houston Company exhibit an electric borer or auger for ore or stone boring." The principal object of the Exhibition is, no doubt, to push the electrical goods of the various French firms, whose manufactures are at the present time in considerable favour in St. Petersburg. A number of these companies are formed for the sale and manufacture of Edison plant, and we understand that they have succeeded in placing their manufactures almost exclusively in Moscow, and have a fair prospect of securing a similar monopoly in St. Petersburg. Electric lighting business is not very brisk in Russia just now, but what there is doing is largely in the hands of French houses.

"THE ENGINEER."—The advertisement and editorial departments of *The Engineer* have been removed to larger offices at 33, Norfolk-street, Strand, London, W.C.

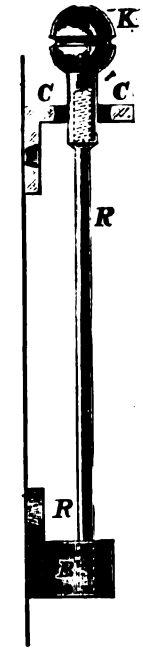
ARCHER PATENT JOINTED STONEWARE PIPES.—These pipes are being used by Messrs. J. H. Gordon and Co. (Limited) as mains for the cables to supply the electric light at the Crystal Palace.

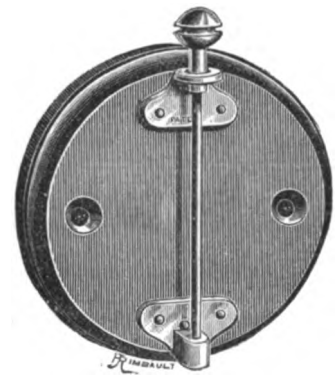
MESSRS. G. E. BELLISS AND CO.—In order to provide the necessary facilities for a rapidly increasing electrical business, Messrs. Belliss and Co. open on the 9th inst. a London office at Westminster-chambers, 9, Victoria-street, S.W., under the management of their London representative, Mr. W. Crawford.

MR. G. G. BLACKWELL.—Mr. Blackwell, of Liverpool, has appointed Messrs. Stobbs, Wilson, and Pollard, 4, Billiter-buildings, E.C., his London agents for the sale of manganese, &c.

BUSINESS CHANGE.—The business of Messrs. Cecil Wray and Co., of Bradford, has been acquired by Messrs. Andrews and Preece (Limited).

MAJOR BAGNOLD'S PATENT IMPROVED BELL-PULLS AND BELL-REPEATERS.—The ordinary push-button must be pressed in a direction at right angles to the surface of the wall or other support to which it is fixed; again, the contact made is not always of the best, it is essentially a "butt" contact, and possesses little or no self-cleaning powers. It is difficult to actuate these push-pieces from any other position; flexible cord connections are also used connected to "pear" pushes, but these are seriously liable to derangement. A diagram and a view of the bell-pull are shown in Fig. 1; a rod of steel, RR, is set vertically with its lower end firmly fixed into a brass block, B; on its upper end is screwed a brass knob K, the shank of which passes through a brass ring CC; the conducting wires are attached to B and C. A slight pressure applied to K in almost any direction other than in that of the axis of the rod RR, will deflect that rod and cause the shank of the knob to touch the ring CC, and make the necessary contact. This contact needs no silvering or platinizing, as the knob can at any time be given a circular motion which will clean the contact surfaces and ensure the establishment of the circuit. If it be desired to actuate this contact-piece from a distance it is only necessary to tie a fine cord round the horizontal groove on knob K, and this cord can be led





FIGS. 1.

off in any required direction such as to a bed, a chair, or a dinner table. This bell-pull can also be conveniently combined with a sound repeater. The repeater is shown in Fig. 2 without the

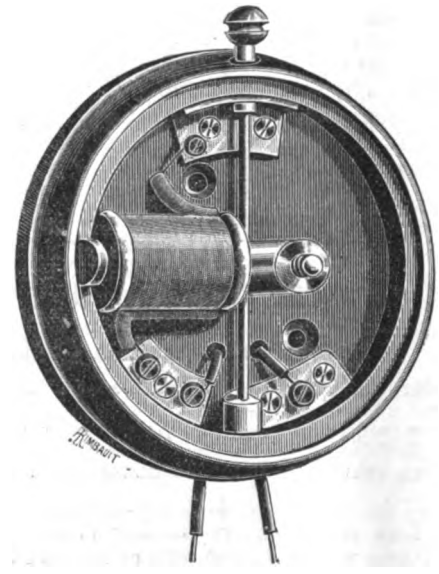


FIG. 2.

dome. When the latter is screwed on, one pole of the electromagnet is presented to the side of the bell; as soon as the contact is closed and the circuit is intermittently interrupted at the distant "chattering" bell, the bell dome of the repeater is set into vibration, and gives out a clear but not inconveniently loud ringing sound. These bell pulls and repeaters are the invention of Major Bagnold, and are made by Messrs. Siemens Bros

WORCESTER.—On Saturday last an effective electric lighting display was shown at Worcester Cathedral to celebrate the return of the Earl and Countess of Dudley. One of the large search lights from the Naval Exhibition was placed on the roof of the Cathedral, added to which four large arc lamps were placed at other points of vantage. The work of installation was undertaken

Digitized by Google

by the British Electric Installation Company, and was under the superintendence of Mr. Morgan Williams, their consulting engineer. Mr. Ronald A. Scott carried out the erection of the plant at the Cathedral.

MESSRS. ERNEST SCOTT AND MOUNTAIN (LIMITED).—This firm inform us that the Earl of Ellesmere has decided to light by electricity the large private house and training establishment now built on his estate at Newmarket, and that the contract has been entrusted to them. The installation is to consist of a 30 I.H.P. horizontal engine, which will be used in driving a specially wound "Tyne" dynamo, supplying current to a set of accumulators capable of running 100 16-candle-power lamps for 10 hours, or the dynamo will supply 200 lamps direct. The engine power will also be utilised for pumping, chaff-cutting, &c.

COMPANIES' MEETINGS & REPORTS.

The Monte Video Telephone Company (Limited).

The annual ordinary general meeting of this Company was held at the Company's offices, 25, Abchurch-lane, E.C., on the 30th ult., under the presidency of Mr. Arthur Holland.

The SECRETARY (Mr. E. Johnson) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN said the accounts for the present year, as compared with those of last year, showed that the receipts from subscriptions had diminished by £2,604, while the London expenses had increased by £75, and the expenses in Monte Video by £1,051. To meet bad debts last year the Company had written off £660, and the amount written off this year on the same account was £852. There was also a loss of £332 by the defalcation of the Company's collector in Monte Video. The consequence was that the net profits of the Company, as compared with last year, had diminished by £5,381. It had caused the Directors considerable regret to have to present a report showing so large a diminution of profit; but he thought, when the shareholders heard the explanation the Directors had to offer, they would be satisfied that no more could have been done to obviate that result. In the first place, the increase of £75 in the London expenses had arisen from the fact that they had been debited with £102 for interest on the money borrowed last year to pay the dividend. The other items of London expenditure had been reduced by small amounts. As regarded the increase of £1,051 in the expenses at Monte Video, he found that wages and salaries there had been reduced by £61, and as a result of steps taken during the past year, they would be considerably reduced in the current year. The rent in Monte Video had increased by £70, owing to the failure of a tenant occupying part of the Company's buildings to pay his rent. That tenant had left and they had to find another. The cost of materials had gone up £766—a large amount. The Company had also been put to considerable expense by reason of the new Municipality of Monte Video compelling them to remove posts from certain of the streets, and a considerable sum of money had to be expended in fresh wires and cables. In explanation, he added, that there was a stipulation in the original concessions to the Company that posts might be erected in roads, but not in streets; and that consequently as the roads became streets by the extension of the town, the removal of the posts originally put up became necessary. Concerning the small items of expenditure, he stated that travelling expenses were about £36 more than in the previous year; stationery was about the same, and there was a slight increase in the expenditure on freights. Addressing himself to the question of bad debts, he acknowledged that this was a serious amount to meet. In the year before last £245 was written off on this account; and last year, owing to the depressed state of all business in Monte Video, the Company had been unable to recover £660 of outstanding bad debts; while this year the amount had risen still more, and they were compelled to write off £852. When intelligence was first received of the defalcation of the collector in Monte Video, the Directors were naturally very much surprised that the manager of the Company there should have permitted such a thing to take place, because the Managing Director when he was last out there laid down certain rules which he considered sufficient to prevent any embezzlement. Further accounts received from the manager at Monte Video, however, showed that he could not have discovered the falsification of the receipts otherwise than by accident, as was eventually the case. Steps had now been taken to try to ascertain if a better system of receipts could be devised. The collector had been insured in a guarantee society for one thousand dollars, but the financial depression had so affected that society that it had gone into liquidation, and nothing could be recovered. Referring to the diminution in the receipts, he stated that the number of subscribers who had withdrawn during the last year was 507, of whom 372 had left for reasons of economy, 69 had failed, 47 had left Monte Video, 17 had gone over to the Co-operative Company, and two assigned no reason for leaving. As a set-off to the number of withdrawals, he was glad to report that 315 new paying subscribers had joined the Company. That was about the natural increase of subscribers in the course of ordinary business, and he could not but think it satisfactory to find that there was such a large accession of subscribers in spite of the depressed state of things in Monte Video. He thought also that the accession of over 300 new subscribers, as against 400 in the previous year, tended to show the good service afforded by the system as now perfected. So far as the Directors knew, there was no better system in vogue. As regarded the balance sheet, it would be seen that £4,500 of the profit had been placed to "depreciation," practically to meet expenditure made in the past. The balance showed that the Company had spent £220,000 on capital account, and that there was a difference between the debtor and creditor side of the accounts of £1,600, against which there stood only a capital of £215,000 and a reserve of £3,000, thus leaving a deficiency of £3,600, which, with the cash in hand necessary to carry on the working of the business—£1,400—accounted for the further £4,500 which had been put to depreciation. So far as the prospects of the business were concerned, much depended upon the state of affairs in Uruguay, but he could not but think that the Company had reached "bed rock" as regarded the minimum number of subscribers. The accounts from the agricultural and pastoral districts of Uruguay were favourable for the coming season; and as the welfare of the towns on the other side of the River Plate depended upon the wool-clip and harvest in those districts, it must be expected that their prosperity would re-act upon the towns. Then the Company would begin to see that their number of sound, paying subscribers increased. Another item that would affect the number of subscribers was the contemplated reduction in the customs and taxation of the country by reason of the new arrangements which the Uruguayan Government was making with its bondholders on this side. If there is a certain relief from taxation the amount saved ought to be put into business, and help trade to flourish. He thought he had very fully stated the whole situation, but would add that the manager at Monte Video had been compelled to use great tact to avoid coming to loggerheads with the Municipality concerning the removal of the posts. They had now, however, come to fair terms. With reference to certain losses by the failure of the National Bank of Monte Video, he stated that those were due to the fact that the manager at Monte Video had to accept notes of that Bank in payment from subscribers, and the loss thus entailed went to swell the bad debts. The Directors expected that the next year would show a diminution of the expenses in London and Monte Video of about £200, and he hoped that next year they would be able to present a much more satisfactory result. He concluded by moving the adoption of the report and statement of accounts.

Mr. THOS. D. PETERS formally seconded.

Mr. BALFOUR said the first idea one would entertain after reading this report would be to ask whether it had been composed by serious men. Referring to an expression in the report, he asked whether the Directors and managers considered it matter for congratulation that whereas the Company three years ago had a monopoly of the telephonic business in Monte Video, there now existed a rival company with 1,000 subscribers. Was it, he asked further, cause for congratulation that the defalcations of the collector had extended over some time without detection? Considering the meagre amount of cash in hand at Monte Video, he inquired whether it was thought possible that the embezzlement could have gone on if the manager there had balanced up his books. He asked also, if it was considered cause for congratulation that the Monte Video manager had allowed things to come to such a pass with the National Bank. Mr. Balfour then entered into a comparison of the balance sheets for the last three years, showing a diminution in the amount of receipts

Digitized by Google

with an increase in expenditure, and concluded by expressing the opinion that the Board did not recognise the gravity of the situation.

The MANAGING DIRECTOR (Mr. Edward F. Powers) thought it was incumbent on him to answer Mr. Balfour, in view of the fact that he held in the Company the position of Managing Director. At the same time he regretted that that gentleman had seen fit, after the very careful and lucid exposition of the position of the Company which he (the speaker) had already given to him, that he should again ask that position to be made clear. Mr. Balfour had concluded his remarks by asking the Directors if they could realise and appreciate the grave position which they were in. But he would like to ask Mr. Balfour whether, in analyzing and criticizing the report, he understood the precise position of affairs in Monte Video. He thought that if that gentleman did so, he would have more of the spirit which prompted the Board to say that it had more cause for congratulation rather than for condemnation. When he reviewed the position in Monte Video—the disasters which had occurred there—during the last year, the failure of the National Bank, its reorganisation, and its second failure, the poverty of the people at large, in short the utter stagnation of all commercial and industrial interests, crippling political affairs, and ending in revolutions, not to speak of other obstacles militating against the conduct of business, he thought they were to be congratulated that they had so much as they possessed. He said this with no superficial idea of the position, but as a man connected with the River Plate; not in offices in Throgmorton-street or on the Stock Exchange, but as one who had lived there and had some practical as well as theoretical knowledge of the Company's business; and he would not withdraw one word of their congratulations. The next point that Mr. Balfour brought to their notice was that the rival companies had 1,000 subscribers. They had 1,000 subscribers before he concluded the transfer to this Company from the old Monte Video Telephone Company, Limited; they had 1,000 subscribers before he had the legal documents in his possession, before he registered the transfer and purchase of the Gower-Bell interest which was sold to this Company by Messrs. Quilter and Henderson, and a copy of which he possessed for the inspection of any person making application. As Managing Director of the Company he had been in negotiation with the opposition Company for the purpose of finding out what their position was. He had been in negotiation with the President and one of the largest shareholders of the property for the purpose of arriving at a common understanding in regard to the working of the two interests; and he could only say that their position was of such an unknown quantity, that it was so doubtful in their own minds, that the President refused to go on with the negotiations in London because of the restrictions in his power of attorney, and actually passed through London without seeing him. Whether the existence of the other company in Monte Video was an annoyance or hindrance to their business he did not know. He presumed that it relatively stood in the position in Monte Video that the Co-operative Company did in Buenos Ayres. He hoped it was no worse. The next point Mr. Balfour referred to was with regard to the defalcations. After six or seven years' experience in receiving moneys from collectors in Buenos Ayres, he had himself instituted a system for checking those men. It was the best that he could devise, but it proved not to be infallible; and the defalcations referred to arose from the fact of the subscribers to their service in Monte Video not taking care to check any receipt they got for money received by the collector in place of the prescribed form; and consequently no power on earth could have found out the defalcations. He would be very glad indeed if anyone could show him a system by which such losses could be saved. As to the National Bank notes, they were received after the failure of the Bank for the simple reason that there was no other money that they could get from the people who owed it to the Company. They had to take the notes or nothing. This might be seen on reference to the file of the manager's letters.

Mr. HENDERSON said that the Bank resumed payment on the 1st July, 1891. If they held any of the notes on the 30th June, he presumed they would be dealt with in next year's accounts.

The MANAGING DIRECTOR said that the last notes taken in by the bank were at a discount of 4 or 5 per cent., according to the best of his recollection. That was the position when those negotiations were going on. There was no power on earth could have saved the losses that they had so openly placed on the face of the accounts. They say that nobody else could have done anything else, because if the Bank of England failed to-morrow its notes would fetch exactly what they were worth, as in the case of the National Bank of Monte Video, and they had to take paper in lieu of gold, and so there was a certain loss incurred. But this course had to be adopted in order to pay their employés, &c. Mr. Balfour referred to what he believed was a comparison of the relative expenses to the income during the last few years. No doubt the figures were correct, but anybody acquainted with telephonic business must be aware that though they had a withdrawal of subscribers here and there, they could not withdraw their employés. If they lost, say 25 lines on a given road, they could not take off the young lady that handled the switchboard, because on those lines other lines existed. Unless a very large number were withdrawn they could not dispense with the men who cleared and repaired the lines. These were natural obstacles to the full and proper development of a telephonic company. They had never been solved in any other part of the world he knew of. If they could be, he could only say that he would take measures, so long as he was connected with the Company, to follow out such a system. He must say that he did not know that there was any business in Uruguay built up with English capital that was stronger in its position than theirs was. He would be very glad indeed to hear how their position could be strengthened in any shape or form. He would like to say, before concluding, with regard to certain rumours he had heard respecting the management, that the only comment he had to make on those rumours was that he held proxies representing £50,000 odd, and he had friends who had come forward to buy a large number of shares; and as a mark of the faith and belief they had in him, he thought that this was the best testimony he could bring forward.

Mr. HENDERSON said he understood there was a proposal to make a change in the management. Had it not been for that he would certainly have proposed an amendment, because, judging from experience, he was afraid of the Company having to go into liquidation. The Directors had no right whatever, according to their showing now, to pay a dividend last year.

The CHAIRMAN said he might state that the reduction of the tariff all round would be a very serious matter; but the manager in Monte Video had been empowered to consider the case of individual subscribers where it was found necessary. The increase of expenses at Monte Video was due to the Company having written off a large amount to maintenance, instead of putting it to capital account, a course recommended by the auditors. With reference to the payment of a dividend last year, he said it looked at that time as if the then prosperity of the Company would continue.

Mr. G. H. SANDFORD asked how many subscribers there were.

The CHAIRMAN said there were 1,400.

Mr. SANDFORD further asked what was the amount lost by taking the National Bank notes instead of gold.

The CHAIRMAN answered £125. He then put the motion, which was carried.

The MANAGING DIRECTOR proposed, and Mr. T. D. PETERS seconded the re-election of Mr. Holland to his seat at the Board.

The motion having been carried unanimously,

The Auditors, Messrs. Gérard Van de Linde and Son, were reappointed, on the motion of Mr. HENDERSON, seconded by Mr. THORNBURY.

Mr. SANDFORD then proposed a vote of thanks to the Chairman, which was seconded by a SHAREHOLDER, and cordially passed.

The CHAIRMAN having briefly returned thanks, the proceedings terminated.

Crompton and Company (Limited).

An extraordinary general meeting of the members of Crompton and Company (Limited) was held at the registered offices of the Company, Mansion House Buildings, Queen Victoria-street, on Tuesday last, for the purpose of considering, and if approved, of passing the resolution set out below. Mr. R. E. Crompton was in the chair.

Mr. FRANCIS R. REEVES (the Secretary) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN said that the shareholders had heard the notice read, and he would now proceed to explain the reason for calling the meeting, which was, as they had stated in the notice, to increase the capital of the Company. It would be recollected that three years ago the Company was a private partnership, which from small beginnings had grown to a not inconsiderable position, and since it had been turned into a Company that growth had been continuous. They had gone on progressing by leaps and bounds, and year after year they had very much increased their percentage: they had increased it as much as 30, 40, and 50 per cent.; and now their turnover was two and a-half times what it was when it was a private firm. The calculations made at the time the Company was formed and the prospectus issued did not anticipate such a great increase, and in consequence they had already found themselves considerably crippled, and they had had to refuse good and valuable orders that had been offered to them because they had not sufficient working capital to carry them out. They had not refused, of course, all orders, but they had had to refuse those which required a considerable amount of working capital to carry them out. They had, however, done a large amount of work with the capital that they had at their disposal, and they had carried it out in a satisfactory manner, and made a good profit, which had enabled them not only to pay the full preference interest, but had left a large margin for the payment of the ordinary shares dividend in addition. They had at the present time considerable offers pending, and the Directors had come to the decision to take steps for increasing the capital of the Company, and they deemed the best way, as stated in the notice issued to the shareholders, was to issue an increase of preference capital. To give the shareholders some further idea of the advantage of ample capital in their particular business he might say that if they had plenty of capital they were able to pay absolutely cash for much of the material which they purchased, and they were not compelled to give three months' limit, whereby they lost considerable discounts. The losses they would be liable to incur in this respect would be overcome and avoided if they obtained this extra capital for which they were now asking. Personally he must say that he would not, being a large holder of ordinary shares—indeed, the ordinary shares were mainly held by the members of the old firm, himself, and Mr. Albright—have allowed the new capital to come in front of the ordinary shares for dividend unless he had felt that in making this increase the results would be increased business that would justify the step, and that they would not lose but gain in the prosperity of the business. It had been suggested to this Board that those shares might have been issued to the shareholders at a premium; but after carefully considering the matter the Board had felt it wise to divide the amount into two, and they proposed to make a first issue of 5,000 new preference shares at par, and to let the present shareholders have the advantage. Their preference shares at the present time stood at a premium—a considerable premium—in the market, and the Directors felt that it was only fair that the existing shareholders should have the benefit. As to the remainder, the Directors would consider whether they would issue them at a premium or not. Although there was a very small attendance of shareholders at that meeting, he would like to state that the Board had obtained the opinion of the general body of the shareholders by means of proxies, and they had received proxies representing more than three-fourths of the shares. He concluded by moving:—

Digitized by Google

"That the capital of the Company be increased by the issue of 10,000 additional preference shares of £5 each, such shares to be numbered 20,001 to 30,000, inclusive, and to rank for preference or priority as regards dividends, and in the distribution of assets, and in all respects pari passu with the already existing preference shares of the Company, and the Directors are hereby authorised to issue these new shares at such times and on such terms as they may think fit."

Mr. J. F. ALBRIGHT (Director) seconded the motion. He stated that he was a very large ordinary shareholder, as the Chairman had said; but he was, like the Chairman, willing to stand aside and allow further preference capital to be placed in front of his ordinary shares, as he believed it was for the ultimate benefit of the Company, and that it would increase their trade, and that they would be able to do a larger business in consequence. He had, therefore, much pleasure in seconding the motion.

The CHAIRMAN invited discussion.

No questions were asked.

The motion was then put, and carried unanimously.

A vote of thanks to the Chairman closed the meeting.

Western and Brazilian Telegraph Company (Limited).

The following is the report of the Directors of this Company to be presented at the twenty-second ordinary general meeting of the Company to be held at Winchester House, London, E.C., on Thursday, the 12th inst., at 12 o'clock:—

The total earnings amount to £104,962 9s. 7d. as against £89,846 13s. 9d., an increase of £15,115 15s. 10d. compared with the half-year to 30th June, 1890. From the above total earnings has been deducted the sum of £11,121 4s. paid in respect of traffic receipts between March, 1889, and December, 1890, hitherto under dispute.

The working expenses amount to £38,638 10s., as against £40,509 13s. 3d., a decrease of £1,871 3s. 3d.

Including the amount brought forward from 1890 (£6,070 6s. 1d.) and the dividend received upon the shares held in the "Platino" Company to the 30th June, the balance to the credit of the revenue account is £79,781 10s. 8d., from which has to be deducted £12.866 10s. for debenture interest, and £6,233 10s. for the debenture redemption fund, leaving £60,681 10s. 8d., of which £25,000 has been placed to the reserve fund. This leaves £35,681 10s. 8d. The Directors recommend the payment of a dividend of 6s. per share, free of Income Tax, on the ordinary shares for the half-year, being at the rate of £4 per cent. per annum, carrying forward £6,470 4s. 8d. At the corresponding period last year the dividend was at the same rate.

The arrangement with the Monte Videan and Brazilian Telegraph Company, already approved by the shareholders, was completed on the 11th June, and 5,300 ordinary shares were issued in exchange for the undertaking of that Company, which has now been wound up.

The new cables between Pernambuco and Bahia, Bahia and Rio de Janeiro, and Rio de Janeiro and Santos have been satisfactorily laid by the contractors, The India Rubber Gutta Percha Telegraph Works Company (Limited). They were duly taken over, and have greatly improved the working of this Company's traffic. The section between Pernambuco and Ceara, which contained the last long length (over 200 miles) of original cable, was interrupted in March, and could not be repaired owing to the type of cable, its condition and the great depth of water. The probability of this happening has been previously referred to, and although this section has now given way it has lasted a considerable time longer than the Directors anticipated. Arrangements were therefore made to send out sufficient new cable in the "Silvertown" to restore communication, and this was successfully done in September.

The dividend warrants will be posted on the 13th November.

NEW COMPANIES, STATUTORY RETURNS, &c.

BICESTER ELECTRICITY SUPPLY COMPANY (LIMITED).—This Company was registered on November 2, 1891, with a capital of £5,000, in £5 shares, by Messrs. Inderman, Clark and Parker, 1, Devonshire terrace, Portland-place, W. It intends to carry on at Bicester the business of an Electricity Supply Company, by constructing, laying down, erecting, fixing, and carrying out the necessary cables, wires, lines, primary, secondary batteries, accumulators, lamps, &c., and to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity, manufacturers of and dealers in apparatus necessary for the generation, distribution, accumulation, and supply of electricity, &c. The subscribers are Messrs. F. Smith, W. Grinsley, J. W. Smith, T. W. Pankhurst, T. C. Fruch, J. Colman, and G. T. Cannon, all of Bicester. Registered without articles of association.

BLAIKIE BROTHERS (LIMITED).—This Company has been registered in Scotland, with a capital of £30,000, in £1 shares. Object:—The purchase of the business, machinery, plant, and effects of Blaikie Brothers, engineers and ironfounders, Footdee Ironworks, Aberdeen, and to carry on the business of engineers, ironfounders, and bridge builders, and iron, steel, and metal merchants.

QUINTON CYCLE COMPANY (LIMITED).—This Company was registered on October 27, 1891, with a capital of £35,000, in £5 shares, by Messrs. Waterlow Brothers and Layton (Limited), Birchin-lane, E.C. The objects are to acquire the business of S. and B. Gorton (Limited), cycle manufacturers, machanical and electrical engineers, &c., and to carry on the same. The first subscriber is Arthur Chamberlain, Esq., J.P., Moor Green Hall, near Birmingham.

STANDARD LAND, BUILDING, AND INVESTMENT COMPANY (LIMITED).—This Company has been formed to deal in land of all kinds, to explore, clear, fence, develop, and turn to account lands acquired by the Company, and to establish and manage public buildings of all kinds, to erect, maintain, and control *(inter alia)* water and gas works, electric light, heat, and power works, telephonic and telegraphic communication, &c. Registered on October 24, 1891, with a capital of £5,000, in £5 shares, by W. R. King, of 25, George-street, Stoke-upon-Trent.

ELECTRIC WELDING COMPANY (LIMITED).—The offices of the above-named Company have been removed from 2, Tokenhouse-buildings, London, E.C., to 6, Great George-street, Westminster, S.W. (Filed on October 26, 1891.)

LAWS' ELECTRICAL APPLIANCES COMPANY (LIMITED).—The first registered office of the above-named Company is situate at 2, Jackson-road, Holloway, London, N. (Filed on October 27, 1891.)

RAILWAY ELECTRICAL CONTRACTORS (LIMITED).—The following notice was filed on October 27, 1891:—"To the Registrar of Joint Stock Companies. I have to inform you that a meeting of the Railway Electrical Contractors (Limited) was duly held on October 23, 1891, pursuant to Section 142 of the Companies' Act, 1862, for the purpose of having an account laid before them, showing the manner in which the winding-up of the Company had been conducted, and that the same was done accordingly. Signature, Frank E. Hersee, liquidator." This Company was registered on March 12, 1884, to develope inventions for the lighting of railways, trains, and carriages by electricity. Its capital was £25,000, in £5 shares, and the first Directors were Sir Daniel Cooper, Bart., James Pender, Esq., and T. M. Collet, Esq. On the date of the last return all the shares had been taken up, of which 4,500 had been issued as fully paid. At extraordinary general meetings, held on July 13, 1889, and July 29, 1889, it was resolved that the Company be wound up, and the Company's business be sold to the Electrical Construction Corporation (Limited); and Mr. F. E. Hersee, of 144, Leadenhall-street, E.C., was appointed liquidator at a remuneration of £500, which included any other claim upon the Company's property.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts of this Company for the week ended November 1st amounted to £802; aggregate receipts for half-year to date, £12,763.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of October were £3,200, as compared with £3,310 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of October were £2,436, as compared with £2,779 in the corresponding period of last year, a decrease of £343.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of October, 1891, amounted to £60,784, against £59,589 in the corresponding period of 1890, being an increase of £1,195.

EASTERN EXTENSION TELEGRAPH COMPANY (LIMITED).—The receipts of this Company for October amounted to £42,246, as against £47,117 in the corresponding period of last year, showing a decrease of £4,871.

ELECTRIC CONSTRUCTION CORPORATION (LIMITED).—In a previous issue we gave a *résumé* of the views held by Mr. W. W. Duncan on the position of this Company's stock, and we give below an extract from his November circular:—"A great deal of good investment business has been done in these shares since I drew attention to the Company in my last report, and I am glad to say that in that short time the Company has acquired at least 250 new shareholders. This, I need hardly say, greatly strengthens the Corporation as well as the market for the shares, as they have taken the place of certain large shareholders who were obliged to sell. The more I look into the prospects of the Company the more I am satisfied it has a most brilliant future before it, and that the shares are ridiculously cheap at anything under the par price. Great steps are about to be taken in the electric lighting of our metropolis, as well as in many of our provincial towns, and this Corporation is bound to get its full share of these profitable contracts either directly or indirectly. I mean by that, supposing it does not get the direct contract for carrying out the work, as it possesses the most complete manufactory for electrical appliances, the contractors are bound to come to it for supplies. Meantime the works are all fully employed, as they have been during the past year, and the report, which will be issued shortly, will give every satisfaction. The present price of the shares includes the dividend for the whole year."

ELECTRIC TRUST (LIMITED).—The prospectus of this Trust was issued early in the current week, and the list of applications for shares closes this day (Friday). The Trust is formed with a capital of £60,200, divided into 6,000 ordinary shares of £10 each and 200 founders' shares of £1 each. Of this capital £20,200 has been privately subscribed, and the remaining 4,000 ordinary shares of £10 each were offered for subscription at par. No Directors' fees are to be paid except out of the profits, and these are limited to £50 per annum for each Director. The Directors are

Digitized by Google

Messrs. Spencer Chadwick, H. S. King. W. R. Renshaw, and Admiral Sir G. Elliot, K.C.B. The consulting engineer is Dr. J. Hopkinson, F.R.S., and the secretary is Mr. Edward Mann, Palace-chambers, Westminster. The prospectus states that the Company was originally established in June, 1889. and consisted of eight members, who subscribed a sum of £2,000 each for the purpose of testing various methods of distributing electrical energy ; and from the experience gained by the old Company, the Directors state that they are satisfied that electricity can be generated and distributed at a cost which will leave an ample margin for profit, where the installations are properly designed and carried out with careful regard to economy and capital. Particulars follow of the working installation on the high-tension alternating system, and also the low-tension system on the installation at Palace-chambers, Westminster, which the old Company established. The objects as disclosed by the prospectus are to assist in the promotion of electric lighting power and traction.

EXETER ELECTRIC LIGHTING COMPANY (LIMITED).—This Company having obtained a Provisional Order for the supply of electricity in Exeter, are issuing £10.000 first mortgage debentures in order to defray the cost of laying mains underground.

GREAT NORTHERN TELEGRAPH COMPANY (LIMITED).—The traffic returns of this Company in October, 1891, were £24.400; January 1st to October 31st, £237.800 ; corresponding period, 1890, £232,800 ; corresponding period, 1889, £229,200.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).— The general meeting of shareholders of this Company will take place at Winchester House, Old Broad-street, E.C., on Tuesday, November 17th. The transfer books of the Company are closed from Wednesday, the 4th to Tuesday, the 17th inst., both days inclusive.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 704.—Vol. XXVIII. FRIDAY, NOVEMBER 13, 1891. PRICE FOURPENCE. *Annual Subscription (U. K.), 19/6.*

NOTES.

Cable makers, and ingenious electricians generally, will do well to take note of the correspondence on "Coast Communication" published in *The Times* of Tuesday last, and of its leader thereon the same morning. When the leading journal takes up a subject of this kind in earnest, we may safely conclude that public opinion has been sufficiently and definitely formed, and that the time for action has arrived. *The Times* repeats only what has been said over and over again for many years past; but the publicity of its advocacy will work greater marvels than all the letters that have ever been written; and its concluding words, "Is England content to let her sailors perish by hundreds for want of a little money or for want of a little care?" will probably awaken a response which no other power could have extorted. But something else remains to be done. Certain links in the chain of a complete system of coast communication involve engineering and electrical problems which have still to be solved; and it is to be hoped, when the time arrives for practical experiments to be renewed, that these difficulties may be more successfully overcome than has yet been the case.

Mr. Heaviside's article in our present issue is devoted to a somewhat abstruse but highly important subject—the use of vectors in analysis. The writer discusses in his usual lively and combative manner the great advantages of vector methods over the ordinary Cartesian or quaternion processes; and points out that these advantages are specially important in connection with physical questions. Comparatively few are familiar with the habits of vectors, mainly owing to the absence of an elementary text-book treating of their properties; and we feel sure that a compact summary of the chief facts about them, together with a demonstration of the ease with which they can be used, will prove of great value. Electrical engineers are constantly dealing with vector quantities, although they may not be aware of the fact.

No conception has proved of more use to electricians than that of lines of force; yet no idea could initially be more abstruse or more purely mathematical. The two properties of a vector, those of magnitude and direction, are exactly typified in lines of force. Here the magnitude corresponds with the strength of the magnetic field, and the direction involved is that of the line of force. But vectors are so little understood that the two properties are generally divided; direction is assumed alone, and the strength of the field is described as containing a certain number of lines of force. By way of improving this, the idea of tubes of force has been suggested; but having been used chiefly by writers of a mathematical bent, it has needlessly alarmed many students. Nor is the idea of direction always allowed to remain in its simplicity; frequently in speaking of the magnetism due to the earth we talk of the horizontal and vertical components. But the division of the field into two parts like this is very artificial and really introduces complication. The resultant magnetic field is the only one which has a real existence; and, if we are considering the matter from a mathematical standpoint, it is to this resultant field that our symbols should refer. It is thus the vector quantity which we should deal with, and not the Cartesian components. For reasons of this kind Mr. Heaviside objects to the use of Cartesian methods, and condemns the use of quaternions on account of their complication. The use of vector analysis appears hard merely because it is unfamiliar.

We print to-day a singularly modest letter from Mr. Whitmell, a gentleman distinguished in a widely different branch of natural science, describing how in 1863 he was in correspondence with Faraday on the subject of the possibility of making a magneto-electric machine excite its own magnets. The letter is interesting not only as affording one more proof that this subject was at that date distinctly "in the air," but as revealing on the one hand a curious ignorance of the prior suggestions of Jacob Brett and of Hjorth, and on the other a curious scepticism as to the practicability of the oft-suggested device. A further point of interest is the supposed necessity of beginning with a battery current—a device also re-suggested in 1867 by more than one of the tribe who rushed to the Patent Office to substantiate their claims to the principle of auto-excitation.

The dispute between the local gas concern and the municipal authorities of Sedan, to which a brief reference is made in our Notes columns this week, is an instance of the difficulties in which our Continental friends are not unfrequently landed by their *penchant* for granting monopolistic concessions. With us the Electric Lighting Act of 1888 expressly states that the granting of a Provisional Order in no way confers a monopoly; nevertheless, it is tacitly understood that so long as "under-

Digitized by Google

takers" carry out their obligations in a proper manner they will not be hampered by undue competition. An honourable understanding of this kind is worth reams of parchment. In the case of Sedan gas was given the monopoly until well into the 20th century, a saving clause being introduced to the effect that the agreement might be incontinently cancelled by the Municipality if the progress of science resulted in any improved mode of lighting, and if that improvement were generally adopted for at least two years in towns of a similar size. About two years ago the local authorities came to the conclusion that the conditions mentioned in the saving clause had arisen by reason of the development of electric lighting, and forthwith granted yet another concession—this time to electricity—with the result that they have been condemned to pay compensation, with legal costs, to the Gas Company. Under the circumstances there is little reason to sympathise with the Municipality of this historic town.

The engines and dynamos at the Cologne Municipal station, which is fully described in our columns this week, are of a type which has become firmly established in Germany. Horizontal engines coupled direct to dynamos have been used for ship-lighting by English makers, but we have no example of such an arrangement in a supply station. An exceptionally slow speed appears to be generally adopted on the Continent; and Sulzer engines, which were represented by a very good specimen at the Paris Electrical Exhibition of 1881, are as popular on the Continent as Willans engines are with us. But price seems to be no object at all in Germany. Not only is an extremely expensive mode of building very common, but these slow speeds necessitate proportionately large dynamos.

The use of an exciter mounted on the same shaft as the alternator has been adopted by Mr. Ferranti and Mr. Mordey in certain cases; but the extra cost of this arrangement at the Cologne station must be very considerable, the weight of the armature of the exciter for the 600 unit being 22 cwt., *i.e.*, about the weight of a 50 H.P. armature as made in England. The interlocking switch arrangements appear to be excellent, and are evidently the design of an electrical engineer and not of an electrician. There is still rather too much crockery and lacquered brass about our English stations, and switchboard making is largely in the hands of instrument makers. The fierce cutting of contracts has much to do with the flimsy and ill-designed work that has been put into some of our engine-rooms. Practically the whole switchboard of one of the London stations was pulled out after the engineer had tried hard to make it do what the contractors intended; and at another it was intended to use an entire set of rather complicated switches for a purpose totally different to that for which the contractors had designed them.

One of the most important matters which Major Marindin had to consider in the course of the Board of Trade inquiry in 1889 was the question of competition between supply companies in the same district. Various arguments were used, and the general idea seemed to be that, on the principle of "the more the merrier," when two companies had the run of one district each would race for the largest number of customers. There exists, however, at the present moment a district within a district which is "served" by no less than three companies, where the pleasing supposition has not been verified by the actual facts. Onslow-square is in this privileged region, and although the House-to-House Company have found it worth while to push their wires through a decidedly less favourable district up to the western limit of the square, no electric supply whatever is to be had by the unfortunate householders, who have wired their houses on the strength of the assurances of canvassers from the Chelsea side.

The Chelsea Company, unlike other supply companies, cannot extend its operations by merely putting down mains in the streets, but is obliged to build battery stations at intervals, and the would-be customers in the Onslow-square neighbourhood are told that there have been great difficulties in getting a site. But the London Electric Supply Company have also a right to supply this district, and for some mysterious reason have agreed to abstain from supplying anybody but their own Directors. The Cadogan Company, which is chiefly remarkable for being the only one in London in which the dynamos are driven in the old-fashioned way by leather belts, supplied only 25 houses during 1890; and at the end of February could only boast of 16 customers in Chelsea, owing to a re-arrangement of districts. The London Company would be glad to have a few more customers when they have surmounted the little difficulties which have been recently inconveniencing them at Deptford; and these, so far as we have heard, might have been more easily remedied if the Company had not declined to avail themselves of the further services of their late engineer.

The one thing that the engineer of a well-arranged supply station yearns for is a good load-factor. He has but little complaint to make about his steam engines, his dynamos are as near perfection as possible, his losses in distributing need not be serious, and he is becoming aware that even his coal bill is a minor matter. What he wants is to give his plant a good long run when it is once started. If a good load-factor is to be found anywhere it should be that of the Hammerfest station, described by our Scandinavian correspondent in another column. A night of 66 days, on the other hand, must tax the smooth running of the bearings, though the staff have plenty of time to contemplate improvements during the period of 71 days when no light is required.

Erratum.—On p. 7 of our last issue read "in *Düsseldorf* the total length of gas main is about 116 kilometres," instead of "in Darmstadt," &c.

Mutual Telephone Company.—There are now 750 subscribers to this Company's Manchester exchange. The Company has, in addition, 38 private wires completed.

Junior Engineering Society.—We are informed that Sir E. J. Reed has been elected President of the Junior Engineering

Digitized by Google

Society, and will deliver his presidential address on the 27th inst.

Paddington.—The Vestry has been informed by the Metropolitan Electric Light Company that it intends to supply all buildings in Paddington with electrical energy at 7d. per Board of Trade unit.

Personal.—Mr. George North has resigned his position as General Manager to Woodhouse and Rawson United, and intends to commence business on the 16th inst. at 90, Queen-street, E.C.

New Book.—We are informed by Messrs. Whittaker and Co. that Mr. Stuart A. Russell's new work on electric light cables and the distribution of electricity will be issued shortly in the "Specialists' Series."

Brighton.—At the last meeting of the Town Council the Lighting Committee reported that on the 26th ult. they had resolved that Mr. Arthur Wright be appointed manager of the Corporation Electricity Undertaking, at a salary of £300 per annum.

Telephonic Communication between Lincoln and Liverpool.—Telephonic communication was established between Lincoln and Liverpool on Thursday last week, when the Mayors of both cities spoke through to each other, and offered congratulations on the success of the enterprise.

Fire at Messrs. Clarke, Chapman, and Co.'s Works.—On Tuesday night a fire occurred at the works of this firm, Park-lane, Gateshead, which resulted in serious damage; the flames also damaged the roof the Sunbeam Lamp Company's works, but the whole of the lamp stock was rescued.

Telegraphic Communication with Mashonaland.—A Reuter telegram from Fort Victoria, Mashonaland, says:—"The extension of the British South African Company's telegraph line from Mafeking and Cape Town to Fort Victoria has now been completed, and an office has been opened at this place."

Aluminium.—Reports from Pittsburg announce that the German military authorities have ordered from a firm in that town immense quantities of waterbottles and cartridge cases made of aluminium. The object is to lighten, as far as possible the weight of the soldiers' accoutrements. No less than 500 tons will be required to execute the orders already received.

Worcester.—At the last meeting of the Watch Committee the subject of electric lighting was again discussed. On the recommendation of the sub-committee, it was resolved to recommend the City Council to authorise the committee to publish advertisements inviting tenders for the construction of electric lighting works, enabling the Council to supply electricity equivalent to 12,000 10 c.p. lamps.

Finchley.—An exhaustive report has been submitted to the Finchley Local Board upon the lighting of their district by electricity by their engineer and surveyor, in which he recommends the adoption of the transformer system. The cost of the installation he estimates at £17,000. At a meeting of the Board, held on 27th ult., it was resolved that an application be made to the Board of Trade for a Provisional Order.

Cutting Telegraph Wires.—At the Mansion House on Wednesday Edward Green was sentenced to one month's imprisonment, in default of £5 fine and £4 damages, for cutting the Exchange Telegraph Company and the Boy Messengers and Electric Call Company's wires in St. Paul's Churchyard. The wires being of a substantial character occupied the accused, who was equipped with a large knife, from 10:30 till midnight.

Royal Scottish Society of Arts.—Prizes and medals have just been awarded by this Society on account of Papers read at the meetings during the session of 1890-91—in all about fifteen. The most valuable award is the Keith prize of £21, given to Dr. R. Milne Murray for his paper "On an Electrical Bench for Physiological Research." Professor A. B. W. Kennedy, Professor T. H. Beare, and Mr. A. R. Bennett are amongst the recipients of awards.

Electric Railways for Berlin.—As a set-off to the Siemens project of elevated electric tramways for Berlin, the Allgemeine Elektricitäts-Gesellschaft has petitioned for a concession for the construction of underground electric railways. The last-named scheme embraces three different lines of railway. The tunnels would consist of large iron tubes, screwed and cemented together. Trains are to be run in each direction at intervals of three minutes. Each train would consist of an engine and three carriages, with accommodation for passengers 120 in all. A speed of 16 miles an hour is to be attained.

Joule's Law.—An experimental demonstration of Joule's law has been furnished by Prof. Robert Spice, of Brooklyn. The method employed is to send a current through a known resistance, immersed in a known quantity of liquid, and also to immerse in the same liquid one set of junctions of a small thermo battery connected with a galvanometer. The other set of junctions are immersed in another vessel in a known volume of the same liquid, in which is another known resistance. If both quantities of liquid are heated by the current to the same temperature the galvanometer will remain at zero, but not otherwise. The results of the experiments show that the rise of temperature of the liquids is proportional to the electrical energy expended.

A Use for Old Incandescent Lamps.—In the *Bulletin de l'Association Belge de Photographie* for July, Prof. F. Leconte has a brief note describing some experiments made by him for the purpose of testing the suitability of the incandescent lamp as an indicator of vibrations. A Khotinsky lamp with a looped filament was placed on one of the supports of the Physical Laboratories of the Ghent Institut des Sciences, and a telescope was fixed on another of the supports, the lamp being lit up from behind. Blows on the floor, which did not affect the mercury troughs usually employed for the purpose in the slightest degree, threw the filament into a state of vibration lasting several seconds. Prof. Leconte points out that a long looped ruptured filament is the best, and that the vacuum must be good and the bulb unblackened.

Leeds Electric Tramway.—The Wigan tramways, which have been worked by steam power, have recently been sold to a syndicate. These lines have not proved a success, and the syndicate consulted Mr. John Waugh, of Bradford, who advised the adoption of electricity as the motive power. On Saturday last Mr. Gee (chairman of the syndicate) brought over several representatives of the Wigan Corporation and of the Hindley, Ince, and Pemberton Local Boards to inspect the Roundhay line. They were met by Mr. Graff Baker, the lessee of the line, had a run on the cars, and visited the power station.—On Tuesday the line was officially inspected by Major-General Hutchinson and Major Cardew. At different points on the route experiments were made with the object of testing the capabilities of the cars in regard to speed, brake-power, and other qualities, and in every instance the results appeared to be quite satisfactory.

Lord Mayor's Show.—A feature in the procession on Monday was "a car emblematical of the Guilds and City of London Institute—wood-carving, turning, modelling, drawing. The car drawn by six horses." To be quite up to date there should have been two "third-year students" conducting an original research.—At the banquet in the evening the Guildhall was, for the first time, lighted by electricity. The light was chiefly given by 14 chandeliers, in two rows of seven each down the hall. Each chandelier had three tiers of lights, the uppermost consisting of 18 8-c.p. incandescent lamps, the second of nine 16-c.p. lamps, and the lowest of five 16-c.p. lamps. The diameters of the tiers decreased from the uppermost to the lowest, so that the lamps were approximately arranged to form an inverted cone. Suspended along the centre of the hall by cables running across it near the roof were three or four 500-c.p. incandescent lamps. The arrangements were carried out by the Brush Company.

Research Studentship.—The Coutts Trotter studentship, of the annual value of £250, for the promotion of original research in natural science, more especially physiology and experimental physics, open to graduates of Trinity College, Cambridge, not being Fellows, who are not of more than seven years' standing from the time of commencing residence, has been awarded to John Walton Capstick, B.A., scholar of the College. Mr. Capstick obtained a first class in the Natural Sciences Tripos,

Digitized by Google

Part I., June, 1890, and a first class in the Natural Sciences Tripos, Part II., June, 1891, being distinguished in chemistry and physics.

Huddersfield.—Appointment Vacant.—The Corporation of Huddersfield being about to erect an electric lighting station, are prepared to receive applications from electrical engineers competent to superintend the execution of the works, the contractors for which are the Brush Electrical Engineering Company. Applications should be addressed to Mr. H. Barber, Town Clerk, Town Hall, Huddersfield, and endorsed "Electrical Engineer," and must be delivered by 25th inst. The officer appointed will be required to devote the whole of his time to the duties. No canvassing will be permitted. For further particulars see our advertisement columns.

The Crystal Palace Electrical Exhibition.—A meeting of the Honorary Council of Advice, and of the Special Committee appointed by the Electrical Section of the London Chamber of Commerce, will be held at the Mansion House at three o'clock on Wednesday, the 25th inst., when a report on the progress of the Exhibition will be presented, and the question of how the Exhibition may best be used as a means of advancing the interests of electrical science will be considered. The Lord Mayor will preside. The whole of the space is now practically allotted, extra buildings having been erected for certain large installations which could not otherwise have been accommodated.

The County Council and the Testing of Meters.—Mr. G. W. Hemming writes as follows in *The Times* of yesterday :—

Much as I may admire the high policy of the County Council, I cannot help thinking that they are a little remiss in the performance of their workaday duties. One of these is to protect the public by testing and certifying the accuracy of the meters supplied by electric supply companies. I am informed by one of these companies who ought to be supplying me with light that they have had 100 meters in the hands of the County Council for six or seven months, and cannot get them back, and that they do not know how much longer I may have to wait before they can put in a meter. As I have already lived nearly two months with my gas put out and nothing to replace it, I think I may fairly complain of the County Council for neglect of duty ; and as my case is only one of a multitude of like instances it does seem that the County Council are wantonly inflicting a grievous inconvenience upon a large number of the constituents whom they tax so freely. If you will kindly insert this letter it may perhaps induce them to moderate their policy of neglect.

Leicester.—About a fortnight ago, on the invitation of Mr. Lennard, the chairman of the Corporation Gas Committee, the members of the Town Council and a large number of other gentlemen, assembled at the Aylestone-road Gasworks to inspect them, and to receive from Mr. Lennard some information respecting electric lighting and the position of the Corporation in relation thereto. Mr. Lennard said it seemed to him that, if electric lighting could be made to pay, they ought to set about taking advantage of their Order at once. The principal question they had to determine, however, was which was the best mode of generating electricity. He was afraid they could not make the concern pay if they generated the electricity by the aid of steam ; and he should be prepared to recommend the Corporation to adopt gas-engines. At present they proposed to have stations in various parts of the town, and not distribute the power from any station over a radius of more than a quarter of a mile. Should the Corporation think it advisable to carry out the Order, a committee would formulate a plan as to where the stations should be placed, and the winter of 1892 should see a good deal of electric lighting in the town.

Islington Vestry.—Messrs. Sharp and Kent are in negotiation with the Islington Vestry with a view of obtaining its sanction to their proposed Provisional Order. Messrs. Sharp and Kent state that they have expended about £10,000 in developing the electric station at the back of Mr. Beale's premises, and they have in contemplation the immediate expenditure of another £5,000. They are supplying about 2,000 lights, besides supplying current to lifts, pumps, &c. At the meeting of the Vestry, when a letter to the above effect from Messrs. Sharp and Kent was considered, a report was received from the Works Committee stating that it had considered the letter from the Board of Trade transmitting copy of letter received from the Postmaster-General with regard to the construction of certain underground electric lighting works in the parish by persons possessing no Parliamentary powers. It was resolved that it was absolutely necessary that a Provisional Order or Licence should be obtained. A letter was also received from the City of London Electric Lighting Company, stating that they proposed to apply for a Provisional Order for the lighting of the parish with electricity, and asking the Vestry to give their sanction.

Gas v. Electricity at Sedan.—An action for breach of contract brought by the Compagnie Française d'Éclairage et de Chauffage par le Gaz, against the Municipality of Sedan, has just been decided in favour of the Gas Company, by the Conseil de Préfecture des Ardennes. An electric lighting concession was recently granted by the town to MM. Colette et Fédrick, in contravention, so the Gas Company alleged, of Article 10 of its concession, which reads as follows :—"It is expressly agreed that if by reason of the progress of science or discovery any new mode of lighting whatsoever shall have been adopted for at least two years in towns of the same importance as Sedan, before the expiration of the present agreement, the Municipality reserves to itself the right of annulling this agreement without compensation, in order to give the town the advantage of the new mode of lighting. Under these circumstances the existing Company will be called upon to enter into a fresh agreement with the town, and, other things being equal, preference will be given to its offer." The Conseil de Préfecture held that the Municipality of Sedan had violated its agreement by authorising MM. Collette et Fédrick to run overhead electric light wires, and that its contention that the clause quoted above did not apply to private lighting could not be sustained. In return for the certain privileges, the Gas Company had bound itself to supply light until January 1, 1917, and the electric lighting concession was an infraction of these privileges, the state of things alluded to in Article 10 not existing. The Municipality was condemned to pay 14,000fr. damages and costs.

The Pittsburgh Street Railway Convention.—We give in another column a sober *résumé* by our New York correspondent of the proceedings at the recent gathering of street railway men at Pittsburgh. The following extracts from the *Electrical World* will show that these proceedings were also of a "lively" character. "The tenth annual convention of the American Street Railway Association at Pittsburgh went off with *éclat*," says our contemporary. "There was a larger attendance, a larger number of exhibits, and larger numbers of places in which to hunt for them than at any previous convention. The delegates were distributed over a greater number of hotels, hunted for each other with more unrewarded pertinacity, and as a consequence did more general kicking than on any similar occasion. The clans began gathering by as early as Monday, October 19th. The large companies who had exhibits for the first comers were a busy crowd, intent on unpacking and arranging machinery, hunting accommodations and getting on the soft side of the Pittsburgh newspaper reporters—all of which feats were accomplished with distinguished success. On all sides of the hotel were displayed cars and trucks. The Thomson Houston, Westinghouse, and Short companies had special cars for the display of their latest motors, while the Edison Company attended to the big residual crowd in the hotel by making the wheels go round in its own rooms. The Westinghouse Company had its standard trucks, including the gearless and an additional magnificent 'bluff' in the shape of one of its single-reduction gear motors running under water in a great tank—not that its street railway motors are intended to run under water, but the exhibition was a fine example of good insulation. On the street car tracks the Thomson-Houston took the warpath with a beautiful long car mounted on radial trucks and equipped with two of the new W.P. motors. The Short Company followed suit with a fine gearless car that carried crowds over the road, while the Westinghouse contingent had a gearless car in regular service, resplendent with flags, and running like a scared cat every time the track was tolerably free of obstructions." After all this, it seems only in keeping to learn that the homeward journey of the delegates was marred by "a prosaic and exasperating freight wreck," and that the Lewis and Fowler cars "pulled into New York seven hours late."

ELECTROMAGNETIC THEORY.—XIX.

BY OLIVER HEAVISIDE.

(Continued from page 709, Vol. XXVII.)

§ 97. Ordinary algebra, as is well known, treats of quantities and their relations. If, however, we examine geometry, we shall soon find that the fundamental entity concerned, namely a straight line, when regarded as an entity, cannot be treated simply as a quantity in the algebraical sense. It has, indeed, size, viz., its length; but with this is conjoined another important property, its direction. Taken as a whole, it is a Vector. In contrast with this, an ordinary quantity, having size only, is a Scalar.

Again, if we consider the mathematics of physical questions, we find two distinct kinds of magnitudes prominently present. All such magnitudes as mass, density, energy, temperature, are evidently quantities in the simple algebraical sense; that is, scalar magnitudes, or simply scalars. A certain (it may be an unstated) unit of density, for instance, being implied, any density is expressed by a simple number. (The question of the "dimensions" of physical magnitudes is not in question.) All magnitudes whatever which have no directional peculiarity and which are specified by a single number are scalars, and subject to scalar algebra.

But such magnitudes as displacement, velocity, acceleration, force, momentum, electric current, &c., which have direction as well as size, and which are fully specified by statement of the size and direction, are vector magnitudes, or simply vectors. Now, just as there is an algebra and analysis for scalars, so is there a vector algebra and analysis appropriate to vectors; and it is the object of the present chapter to give a brief account of the latter, especially in respect to its application to electromagnetism.

§ 98. Algebraical or analytical geometry in the usual Cartesian form, though dealing ultimately with vectors, is not vectorial algebra. It is, in fact, a reduction to scalar algebra by resolution of every vector into three rectangular components, which are manipulated as scalars. Similarly, in the usual treatment of physical vectors, there is an avoidance of the vectors themselves by their resolution into components. That this is a highly artificial process is obvious, but it is often convenient. More often, however, the Cartesian mathematics is ill-adapted to the work it has to do, being lengthy and cumbrous, and frequently calculated to conceal rather than to furnish and exhibit useful results and relations in a ready manner. When we work directly with vectors, we have our attention fixed upon them, and on their mutual relations; and these are usually exhibited in a neat, compact, and expressive form, whose inner meaning is evident at a glance to the practised eye. Put the same formula, however, into the Cartesian form, and—what a difference! The formula which was expressed by a few letters and symbols in a single line, readable at once, sometimes swells out and covers a whole page! A very close study of the complex array of symbols is then required to find out what it means; and, unless the notation be thoroughly symmetrical, it becomes a work of time and great patience. In this interpretation we shall, either consciously or unconsciously, be endeavouring to translate the Cartesian formula into the language of vectors.

Again, in the Cartesian method, we are led away from the physical relations that it is so desirable to bear in mind, to the working out of mathematical exercises upon the components. It becomes, or tends to become, blind mathematics. It was once told as a good joke upon a mathematician that the poor man went mad and mistook his symbols for realities; as M for the moon and S for the sun. There is another side to the story, however. If our object be ultimately physical, rather than mathematical, then the more closely we can identify the symbols with their physical representatives the more usefully can we work, with avoidance of useless—though equally true—mathematical exercises. The mere sight of the arrangement of symbols should call up an immediate picture of the physics symbolised, so that our formulæ may become *alive*, as it were. Now this is possible, and indeed, comparatively easy, in vectorial analysis; but is very difficult in Cartesian analysis, beyond a certain point, owing to the geometrically progressive complexity of the expressions to be interpreted and manipulated. Vectorial algebra is the natural language of vectors, and no one who has ever learnt it (not too late in life, however) will ever care to go back from the vitality of vectors to the bulky inanimateness of the Cartesian system.

§ 99. But supposing, as is generally supposed, vector algebra is something "awfully difficult," involving metaphysical considerations of an abstruse nature, only to be thoroughly understood by consummately profound metaphysico-mathematicians, such as Prof. Tait, for example. Well, if so, there would not be the slightest chance for vector algebra and analysis to ever become generally useful; and I should not be writing this, nor should I have, for several years past, persisted in using vector algebra in electromagnetic theory—a prophet howling in the wilderness. It will readily be concluded, then, that I believe that the vector analysis is going to become generally used in scientific work, and that what is needed is not "awfully difficult." There was a time, indeed, when I, although recognising the appropriateness of vector analysis in electromagnetic theory (and in mathematical physics generally), did think it was harder to understand and to work than the Cartesian analysis. But that was before I had thrown off the quaternionic old-man-of-the-sea who fastened himself on my shoulders when reading the only accessible treatise on the subject—Prof. Tait's Quaternions. But I came later to see that, so far as the vector analysis I required was concerned, the quaternion was not only not required, but was a positive evil of no inconsiderable magnitude; and that by its avoidance the establishment of vector analysis was made quite simple and its working also simplified, and that it could be conveniently harmonised with ordinary Cartesian work. There is not a ghost of a quaternion in any of my papers (except in one, for a special purpose). The vector analysis I use may be described either as a convenient and systematic abbreviation of Cartesian analysis; or else, as Quaternions without the quaternions, and with a simplified notation harmonising with Cartesians. In this form, it is not more difficult, but easier to work than Cartesians. Of course you must learn how to work it. Initially, unfamiliarity may make it difficult. But no amount of familiarity will make Quaternions an easy subject.

Maxwell, in his great treatise on Electricity and Magnetism, whilst pointing out the suitability of vectorial methods to the treatment of his subject, did not go any further than to freely make use of the idea of a vector, in the first place, and to occasionally express his results in vectorial form. In this way his readers became familiarised with the idea of a vector, and also with the appearance of certain formulæ when exhibited in the quaternionic notation. They did not, however, derive any information how to work vectors. On the whole, I am inclined to think that the omission of this information has not tended to impede the diffusion of a knowledge of vector analysis. For, had he given an account of the theory, he would certainly have followed the Hamilton-Tait system; and this would probably, for reasons I shall shortly mention, have violently prejudiced his readers against the whole thing.

But the diffusion of vector analysis has, undoubtedly, in my opinion, been impeded by the absence of sufficiently elementary works on the subject, with a method of establishment of principles adapted to ordinary minds, and with a conveniently workable notation. For the reader of Maxwell's treatise who desired to learn to work vectors in analysis had either to go to Hamilton's ponderous volumes, or else to Prof. Tait's treatise. The former are out of the question for initiatory purposes. But the latter is excessively difficult, although described as "an elementary treatise"—not the same thing as "a treatise on the elements." The difficulty arises in a great measure from the quaternionic basis.

§ 100. Suppose a sufficiently competent mathematician desired to find out from the Cartesian mathematics what vector algebra was like, and its laws. He could do so by careful inspection and comparison of the Cartesian formulæ. He would find certain combinations of symbols and quantities occurring again and again, usually in systems of threes. He might

Digitized by Google

introduce tentatively an abbreviated notation for these combinations. After a little practice he would perceive the laws according to which these combinations arose and how they operated. Finally, he would come to a very compact system in which vectors themselves and certain simple functions of vectors appeared, and would be delighted to find that the rules for the multiplication and general manipulation of these vectors were, considering the complexity of the Cartesian mathematics out of which he had discovered them, of an almost incredible simplicity. But there would be no sign of a quaternion in his results, for one thing; and, for another, there would be no metaphysics or abstruse reasoning required to establish the rules of manipulation of his vectors. Vector analysis is, in its elements, entirely independent of the exceedingly difficult theory of Quaternions; that is, when the latter is treated quaternionically *ab initio*.

"Quaternion" was, I think, defined by an American schoolgirl to be "an ancient religious ceremony." This was, however, a complete mistake. The ancients—unlike Prof. Tait—knew not, and did not worship Quaternions. The quaternion and its laws were discovered by that extraordinary genius Sir W. Hamilton. A quaternion is neither a scalar, nor a vector, but a sort of combination of both. It has no physical representatives, but is a highly abstract mathematical concept. It is the "operator" which turns one vector into another. It has a stretching faculty first, to make the one vector become as long as the other; and a rotating faculty, to bring the one into parallelism with the other.

Now in Quaternions the quaternion is the master, and lays down the law to the vector and scalar. Everything revolves round the quaternion. The laws of vector algebra themselves are established through Quaternions, assisted by the imaginary $\sqrt{-1}$. But I am not sure that any one has ever quite understood this establishment. It is done in the second chapter of Tait's treatise. I never understood it, but had to pass on. That the establishment is not demonstrative may be the reason of the important changes made therein in the third edition. But it is still undemonstrative to me, though much improved. Now this relates to the very elements of the subject, viz., the scalar and vector products of a pair of vectors, the laws of which are quite plain in the Cartesian mathematics. Clearly, then, the quaternionic is an undesirable way of beginning the subject, and impedes the diffusion of vectorial analysis in a way which is as vexatious and brain-wasting as it is unnecessary.

§ 101. Considering the obligations I am personally under to Prof. Tait (in spite of that lamentable second chapter), it does seem ungrateful that I should complain. But I have at heart the spread of a working knowledge of elementary vector analysis quite as much as Prof. Tait has the extension of the theory of Quaternions. Besides, Prof. Tait has assumed a very conservative attitude in relation to Hamilton's grand system. For instance, to "more than one correspondent" who had written for explanation of something they found obscure—and the same thing occurred to me—described in his treatise by "It is evident, . . .", he, "on full consideration," decides not to modify it, but to italicise the words! He also told them that if they did not see it, in the light of certain preceding parts of the treatise, then they had "begun the study of Quaternions too soon" (Third edition, p. 110). This is as characteristic of the sardonic philosopher as a certain heavy kind of "flippancy" is of the Cockney. Again, in his Preface he states one cause of the little progress made in the development of Quaternions to be that workers have (especially in France) been more intent on modifying the notation or the mode of presentation of the elementary principles, than in extending the application of the calculus. "Even Prof. Willard Gibbs must be ranked as one of the retarders of quaternionic progress, in virtue of his pamphlet on Vector Analysis, a sort of hermaphrodite monster, compounded of the notations of Hamilton and Grassmann." Grassmann, I may observe, established, *inter alia*, a calculus of vectors, but not of quaternions.

Prof. W. Gibbs is well able to take care of himself. I may, however, remark that the modifications referred to are evidence of modifications being felt to be needed; and that Prof. Gibbs' pamphlet (Not Published, Newhaven, 1881-4, pp. 83), is not a quaternionic treatise, but an able and in some respects original little treatise on vector analysis, though too condensed and also too advanced for learners' use; and that Prof. Gibbs, being no doubt a little touched by Prof. Tait's condemnation, has recently (in the pages of *Nature*) made a powerful defence of his position. He has by a long way the best of the argument, unless Prof. Tait's rejoinder has still to appear. Prof. Gibbs clearly separates the quaternionic question from the question of a suitable notation, and argues strongly against the quaternionic establishment of vector analysis. I am able (and am happy) to express a general concurrence of opinion with him about the quaternion, and its comparative uselessness in practical vector analysis. As regards his notation, however, I do not like it. Mine is Tait's, but simplified, and made to harmonise with Cartesians.

§ 102. In Quaternions, the square of a unit vector is -1. This singular convention is quaternionically convenient. But in the practical vector analysis of physics it is particularly inconvenient, being indeed, an obtrusive stumbling-block. All positive scalar products have the *minus* sign prefixed; there is thus a want of harmony with scalar investigations, and a difficulty in readily passing from Cartesians to vector and conversely. My notation, on the other hand, is expressly arranged to facilitate this mutual conversion.

As regards the establishment of the elementary vector algebra, that is quite simple (freed from the quaternion); it all follows from the definitions of a vector and of the vector and vector products of a pair of vectors.

Now I can imagine a quaternionist (unless prejudiced) admitting the simplicity of establishment and of operation, and the convenience of the notation, and its sufficiency for practical requirements up to a certain point; and yet adding the inquiry whether there is not, over and above this vector analysis, a theory of Quaternions which is overlooked. To this I would reply, Certainly, but it is not food for the average mathematician, and can, therefore, never be generally used by him, his practical requirements being more suitably satisfied by the rudimentary vector analysis divested of the mysterious quaternion. This does not exclude the important theory of Δ and its applications. Prof. Gibbs would, I think, go further, and maintain that the anti- or ex-quaternionic vectorial analysis was far superior to the quaternionic, which is uniquely adapted to three dimensions, whilst the other admits of appropriate extension to more generalised cases. I, however, find it sufficient to take my stand upon the superior simplicity and practical utility of the ex-quaternionic system.

We may, however, if we wish to go further, after ex-quaternionic establishment of vector algebra, conjoin the scalar and vector, and make the quaternion, and so deduce the whole body of Quaternions. But sufficient for the day is the labour thereof; and we shall now be concerned with scalars and vectors only. The reader should entirely divest his mind of any idea that we are concerned with the imaginary $\sqrt{-1}$ in vector analysis. Also, he should remember that unfamiliarity with notation and processes may give an appearance of difficulty that is entirely fictitious, even to an intrinsically easy matter; so that it is necessary to thoroughly master the notation and ideas involved. The best plan is to sit down and work; all that books can do is to show the way.

Errata.—I should be obliged if those who honour me by reading my articles would make these corrections on p. 709, Art. XVIII.:—

In equation (14) transpose S and S_i.

In equation (25) delete $= L_i/L = M_i/M$, and add a new equation, namely, $x^2 = L_i/L = M_i/M$.

In equation (33) for ρ read ρ/c.

I may add that the quickest way of comparing irrational with rational quantities is by equating corresponding expressions for the energy in given cases, rather than by going to central forces, which is principally useful from its following the ordinary method.

(To be continued.)

A PLAN OF CONNECTIONS FOR EFFECTING SEVERAL TESTS WITH ONE GALVANOMETER.

BY E. H. DRAPER.

By means of the plan of connections sketched in the accompanying diagram, *seven* different tests, most useful on ship or in shore testing-rooms, may all be taken with the same galvanometer. These tests are as follows:—

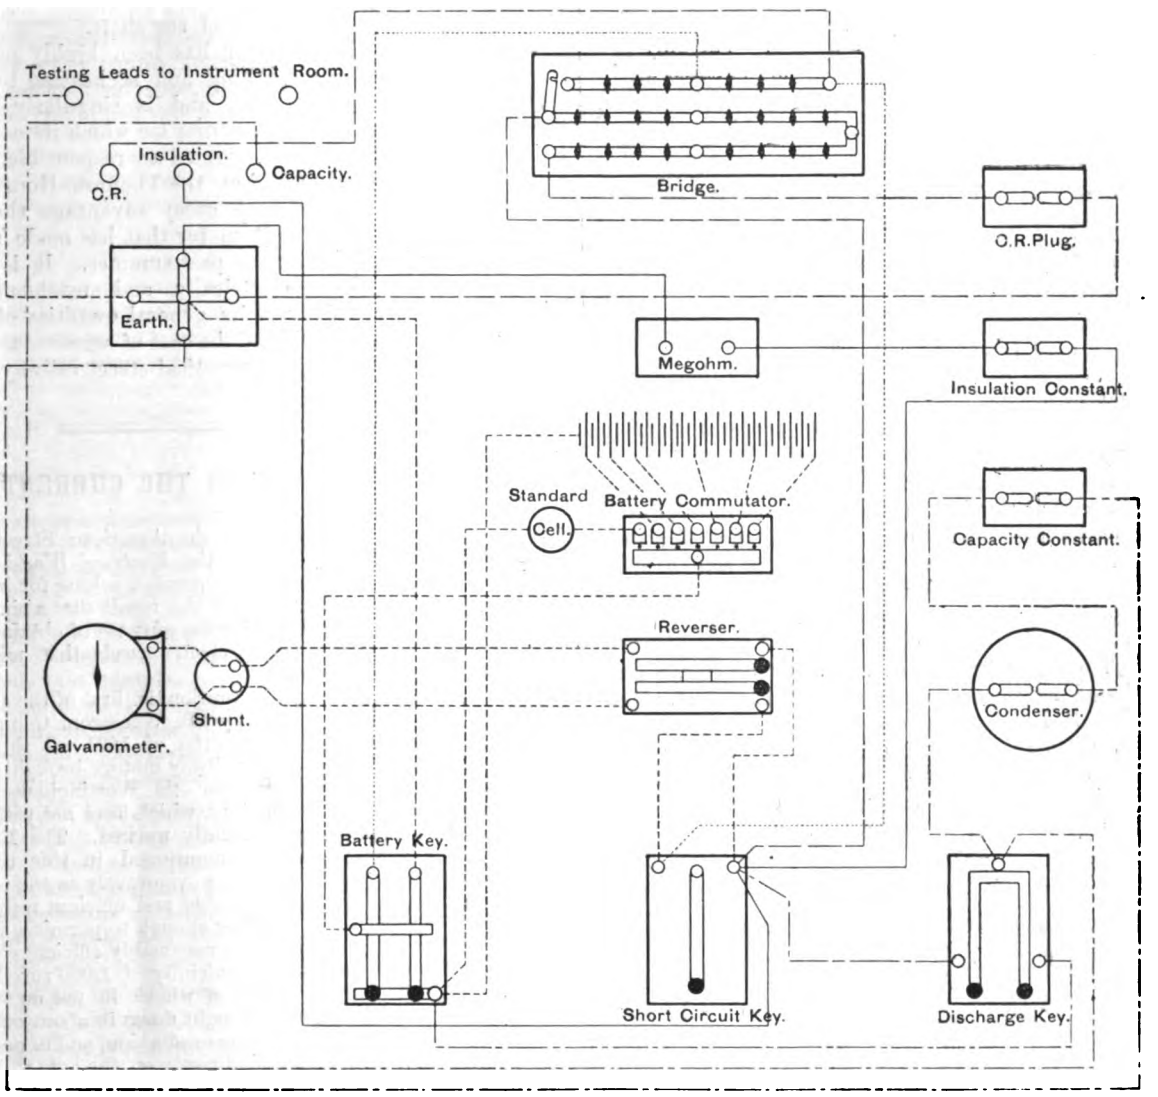

DIAGRAM OF CONNECTIONS.

Connections common to all
C. R.
Capacity
Insulation
C. R. and Insulation

(1.) C. R. = Join up the C. R. Plug and the arm of the Bridge, which otherwise leave open.
(2.) Insulation = as per sketch.
(3.) Insulation Constant = Plug in Insulation Constant Plug.
(4.) Capacity = as per sketch.
(5.) Capacity Constant = Plug in Capacity Constant Plug.
(6.) Battery Resistance = Same as No. 3.
(7.) Electromotive Force of Batteries = By comparison, through Condenser, with Standard Cell. Same as No. 5.

This plan of connection requires little or no changing of plugs or connections, and is therefore more reliable. As seen in the sketch, there are three terminals marked "C. R.," "INSULATION," and "CAPACITY," which are joined for either test, to one of the testing leads. For insulation and capacity no changes are required, simply testing as usual with short circuit key for insulation and discharge key for condenser. For the tests for insulation and capacity constants, simply join up plug commutator in either case, as shown in sketch. For battery resistance, take by half deflection method, using insulation constant. For electromotive force of a battery use capacity constant, and compare with standard cell, in connection with battery commutator. In all foregoing tests be careful that the arm of bridge cuts off connection, as shown in sketch. For C. R. join up the arm of the bridge and plug in bridge commutator, being careful that all other plugs are out; also join testing lead to C. R. terminal.

THE THOMSON-HOUSTON W.P. RAILWAY MOTOR.*

One of the most interesting exhibits at the Pittsburg Street Railway Convention was a new slow speed railway motor of the Thomson-Houston Company, of which the accompanying illustrations give an excellent idea. It has been in process of evolution for six months or more, and has been worked up under the careful superintendence of Mr. Walter Knight.

* From *The Electrical World*.

Digitized by Google

The new machine embodies some decidedly novel features, and its excellent performance on the special car equipped with it was very favourably commented upon. It is known to the trade as the W.P. motor, which being interpreted means water proof, and it well deserves the name, because of the particularly complete ironclad character of the field magnets.

Fig. 1 gives a perspective view of the motor, and from it the arrangement of the iron is at once obvious. Singularly enough, it is a two-pole machine, so arranged on the theory that the comparatively slight gain in weight efficiency that could be obtained with a multipolar type is more than offset by the increased complication of the windings. The only portions of the machine open to the outside air are exposed at the

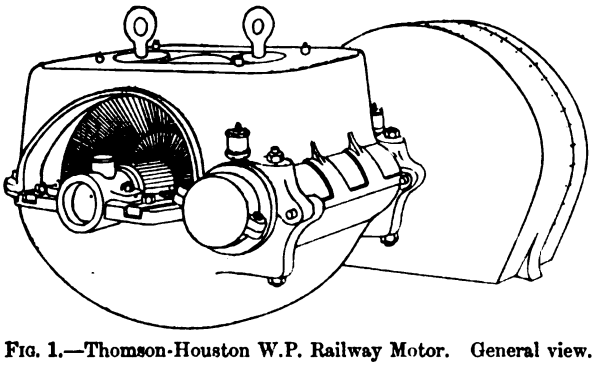

FIG. 1.—Thomson-Houston W.P. Railway Motor. General view.

two oval openings at the ends of the armature shaft, and even these can be easily fitted with covers should such a course prove desirable. The whole magnetic circuit is composed of two castings, bolted together, and free to swing apart by a hinge, allowing ready access to the armature.

Fig. 2 gives an excellent idea of the internal arrangements. The armature itself is very nearly 20in. in diameter, a very powerful Pacinotti ring nearly 6in. on the face, and of about the same depth. It is wound with comparatively coarse wire in 64 sections, with 14 turns to the section. Each coil is tightly placed in the space between two of the projecting teeth, and about the interior space the separate coils are closely packed, leaving only sufficient room for the four-armed driving spider.

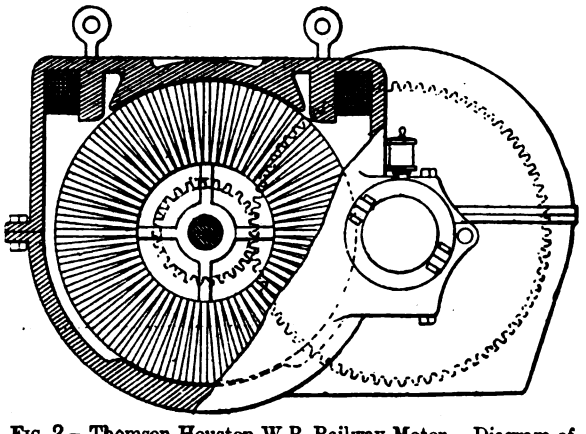

FIG. 2.—Thomson-Houston W.P. Railway Motor. Diagram of Magnetic Circuit.

As will be seen, the armature takes up most of the full height of the machine, the pole pieces being but trifling projections, and the requisite cross-section of iron being obtained by extending the poles to form a closely fitting iron box that appears in the exterior view. An unusual feature is the use of but a single magnetising coil wound not directly about the upper pole-piece but on the casing immediately surrounding it. The lower pole is but slightly raised, and both pole-pieces are of the greatest extent permissible with the dimensions of the machine. The use of a single magnetising coil produces naturally an unbalanced field and a strong upward pull on the armature tending to relieve the pressure on the bearings. The iron-clad form, however, tends to distribute the lines of force so as to avoid the sparking and change of lead that might otherwise have to be feared. The single coil is wound with quite coarse wire, and its position ensures the maximum magnetic effect from the current.

The speed of the new motor is about the same as that of the older S.R.G. form, but its general working efficiency is somewhat better, owing not so much to a greater maximum of efficiency as to a better working curve—at both heavy and light loads. The brush holders are shown in the cut (Fig. 1), and the slots in which they fit render their position evident. The brushes are of the ordinary carbon description, and are readily accessible through the opening at the end of the shaft.

In operation the W. P. motor has been highly satisfactory. It runs with but trifling sparking and no heating to speak of, gives a very powerful torque, and is singularly free from liability to damage of the armature, for which its careful insulation and the Pacinotti form adopted are responsible. It is now being regularly manufactured at the Thomson-Houston works, and it is expected to take with great advantage the place in popular favour of the R. S. G. motor that has made so good a reputation for itself during the past summer. It is an interesting departure, both electrically and mechanically, and aside from its special features its general qualities of iron-clad fields, gears running in oil, and the ease of access to the working parts, will commend it to the practical street railway man.

ELECTRIC RAILROADING IN THE CURRENT YEAR.*

Just before the convention of the American Street Railway Association at Buffalo a year ago, the *Electrical World* sent out a circular to electric street railway companies, asking for information on various points; and so useful was the result that a similar paper was sent out about a month ago for the purpose of obtaining certain facts regarding the operation of electric roads that might prove useful to street railway men.

At the last Street Railway Convention the first of the really slow-speed motors—that brought out by the Wenstrom Company—was exhibited. During the early months of 1891 all the principal manufacturers of electric street railway motors brought out single reduction machines, and two of them—the Westinghouse and Short Companies—devised gearless motors, which have not yet, however, been much more than experimentally worked. The Eickemeyer gearless motor should also be mentioned in this connection, although it has not been exploited so vigorously as the others. It was no small task to produce a durable and efficient railway motor possessed of an armature speed low enough to permit a single-gear reduction. The older motors were reasonably efficient electrically, but the armature speed was in the vicinity of 1,000 revolutions per minute. With the standard sizes of wheels in use on street cars, this armature speed had to be brought down to about one-third its usual value to permit of a single-gear reduction, and to one-tenth to allow gearless machines mounted directly on the axle to be used at ordinary speeds.

To accomplish either of these feats, retaining at the same time a tolerable efficiency, has been no easy matter. To produce the necessary turning effort on the axle a slow-speed motor armature must be constructed so as to have a torque very much greater, and its windings much more powerful than in the case of the old armatures. This increased torque has to be obtained by increasing the induction through the magnets, the number of armature turns, and the current through the armature; sufficient increase in any one of these will answer the purpose, but practically all three are necessarily varied, for in the effort to build a light-weight motor even the double reduction gear machines had the iron worked up practically to saturation, a large number of turns of wire on the armature, and a considerable current flowing through it. A certain gain can be made by constructing multipolar machines, thus making the armature wire in part do double service, but the help is not so great as might at first sight appear. A great deal of ingenuity was spent in combining the three factors of the torque in such a way as to obtain the best results. The multipolar construction has been rather a favourite, and the changes have been in the direction mainly of more powerful armatures, wound with more turns of wire and with coarser wire. So far as the single reduction gear motors are concerned, the problem has been solved with a fair degree of success; in fact, only one of those brought out within the year has proved so unsatisfactory as not to be adopted to any extent. When it came, however, to reducing the speed of the armature, not to one-third of its former value but to one-tenth, the difficulties were enormously enhanced, and in

* Abstracted from the *Electrical World*.

Digitized by Google

neither of the designs brought out has it been thoroughly evident whence the enormous torque required can come. Both forms are reported to do well in comparatively light work, but what would be the results when tried on the same service now exacted of the standard motors it is impossible at present writing to say, as neither type has yet been adopted widely enough to permit any judgment based on everyday experience to be made.

The single reduction gear motors have in general proved an unqualified success, thus amply justifying the predictions of the result that have at various times been made. As regards the efficiency of these new types of machines, appearances indicate that rather more is saved in the gearing than is lost in purely electrical efficiency, so that the total result is rather better than with the old motors. The general adoption of the Gramme type of armature for this work has decreased armature repairs, and accompanying improvements in design have probably raised the mean working efficiency at least 5 per cent.; all this means better and more economical service.

As regards power station practice the indications are that it has improved. The tendency has been to the use of larger dynamos, large and more economical compound or triple expansion engines, and a better proportioning of the plant to the average power required. One marked change has taken place in car equipments; the double truck car exhibited and very much commended at the last convention has proved one of the forerunners of a considerable number of long electric cars provided with bogie trucks or with the excellent radial truck gear that has been recently introduced. Such cars have been rendered necessary by the requirements of electric service. So long as the speeds employed were comparatively low ordinary street car trucks or special forms designed better to support the motors proved quite sufficient for all requirements; as soon, however, as it became necessary to increase the speed considerably a fixed wheel base, comparatively rigid in spite of every effort at flexibility, becomes unsuited to the work, and in addition it is sometimes convenient to use large and very capacious cars. As a result of this a large number of companies are now running, more or less, the long electric cars; they are most serviceable on the larger roads, where they will seldom have to be run lightly loaded. Such cars have to a considerable extent replaced the regular employment of trail cars, although these are most convenient for handling an occasional increase in traffic.

Coming now to the reports received in response to our inquiries, the car mileage properly comes up for consideration. The average is not greatly increased over the figure 101 given by the average of last year's reports; the maximum car mileage, however, is noticeably high. The largest mileage reported was from a small Thomson-Houston road that had been in operation about three months. The President of the company stated that the cars made 175 miles a day, a figure a good deal in excess of the maximum found in last year's reports. Two other roads, a Sprague-Edison and a Westinghouse, both of small size, reported a daily car mileage of 160, while a considerable number reported from 125 to 150; from this the figures ranged down to 46 as the average day's run.

Comparatively speaking, so few roads, even now, are employing single reduction motors that the replies to the questions concerning the operation of these were not as extended as might have been wished. Reports, however, were received from one or more representatives of each of the following systems:—Edison, Thomson-Houston, Wightman, Sperry, Westinghouse, Sieberling, and Baxter. Every road reports entire success. In each case it is stated that the motors start well on grades (in one case noted as 7½ per cent.), do not heat much, seem to take about the same current as the old machines unless possibly a little more in starting, and can perform the heaviest service of the road in a thoroughly satisfactory manner. The reports are uniformly of the most encouraging character, and one or two superintendents wrote in detail to say that they were especially pleased with the performance of the new type of machine. One reports that the single reduction gear machines are working regularly over grades as high as 8 per cent., and sharp curves on inclines only a trifle less severe. Another road is in the habit of taking two trailers up a 6½ per cent. grade with a pair of 20 H.P. motors on the motor car. All this ought to be exceedingly satisfactory both to the street railway men and to the manufacturers of the machines, and leaves no question as to the success of the single reduction motor, which is bound to drive out the older types very rapidly.

The reports on repairs were of a rather singular character; they were surprisingly good, some of them almost too good, in fact. It is certainly very remarkable, for instance, to have a road operating 10 or 12 cars report no armature or field coils replaced or rewound, and no other apparatus disabled during an entire year's operation. On the other hand, the average result of the replies may not be far from correct, for one disgusted street car man reported the cost of repairs on the car equipments as probably reaching $1,000 per car per year. It is very difficult to get at the true cost of necessary repairs on motor equipments, because those who have suffered do not usually care to disclose the full extent of the injury. The reports received indicate, as might have been predicted, that the principal mortality is in armatures, at least three of these being seriously damaged to one field coil, rheostat, or switch-box, and the general tenor of the present reports seems to show that as regards armatures there has been perceptible improvement within the last year. Next year, thanks to the single reduction motors with their big Gramme armatures, the results will unquestionably be even more favourable than at present. The same is true in the matter of gears, for the open gear of the old double reduction motors was, and is, particularly subject to wear and breakage, owing to multiplicity of wheels and to free access of grit and dirt of every description. The later motors with single gears run in oil should, and undoubtedly will, show a very much lessened wear and tear and vastly decreased repair bills.

As regards systems other than the overhead lines, there is very little to say at present. A single storage battery road has been put into operation during the year, and that one is stated to have given very satisfactory results, although no detailed report was sent in. Several other storage battery roads are threatened, together with divers conduit roads of sundry descriptions, but none of them has materialised sufficiently to be given a place here. Altogether the past year has been fruitful in improvements in electric traction, and there are more to come. The directions from which they must be expected are the more general use of the single reduction motor, the improvement of the gearless machines so as to be thoroughly available—at least for light service—the increased use of long and capacious cars on large roads, the displacement of wasteful engines by more economical types of a size better suited to the work, and finally the invention of that ideal piece of apparatus for which every pious street railway man is devoutly praying—a lightning arrester that will effectively protect his dynamos.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

FRIDAY, November 13th. (To-night.)

INSTITUTION OF ELECTRICAL ENGINEERS.

7 p.m. Annual Dinner at the Criterion Restaurant, Piccadilly.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' meeting. Papers to be read:—(1.) "Description of the Works on the Barking and Pitsea Extension Railway." By Henry E. Stilgoe, Stud. Inst. C.E. (2.) "Rail-Pile Bridges in Ceylon." By Harry Bucknall, Stud. Inst. C.E.

TUESDAY, November 17th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Papers to be read with a view to discussion:—(1.) "Portland Cement, its Manufacture, Use and Testing." By H. K. Bamber. (2.) "The Inspection of Portland Cement for Public Works." By A. E. Carey, M. Inst. C.E. (3.) "The Influence of Sea-Water upon Portland Cement, Mortar, and Concrete." By William Smith, M. Inst. C.E.

WEDNESDAY, November 18th.

ROYAL METEOROLOGICAL SOCIETY.

7 p.m. Ordinary meeting. Papers to be read:—(1.) "Report on the International Meteorological Conference at Munich, September, 1891." By Robert H. Scott, F.R.S. (2.) "On a New Self-Recording Rain Gauge." By W. J. E. Binnie, B.A. (3.) "On Wet and Dry Bulb Formulæ." By Prof. J. D. Everett, F.R.S. (4.) "Results of Meteorological Observations made at Akassa, Niger Territories, May, 1889, to December, 1890." By Frank Russell, F.R.Met.Soc.

SOCIETY OF ARTS.

8 p.m. Ordinary meeting. Opening Address by the Attorney-General, Sir Richard Webster, M.P.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m. Special meeting to consider new bye-laws.

THURSDAY, November 19th.

INSTITUTION OF CIVIL ENGINEERS.

2 p.m. Students' visit to Messrs. Samuda Brothers' Works Poplar.

CHEMICAL SOCIETY.

8 p.m. A Lecture on "Colour Photometry." By Capt. W. de W. Abney, F.R.S.

FRIDAY, November 20th.

PHYSICAL SOCIETY.

5 p.m. Paper to be read:—"A New Theory concerning the Constitution of Matter." By Dr. C. V. Barton.

Digitized by Google

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices:
SALISBURY COURT, FLEET ST., LONDON, E.C.
Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co." *All Editorial letters to be addressed to the Editor.*

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from Publishing Offices as above.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Old Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—

PUPILS AND THEIR PREMIUMS.

The exact relationship between master and apprentice was well understood a century or so ago, when generation after generation of workmen passed through the same course. To-day their relative position is less well defined, not because the rules have become vague, but because new ones are continually invented and imposed by the trades unions. A century ago there was no such thing as the premium pupil, and to-day a specimen of the all-round millwright is hardly to be found. Engineering, then a trade, is now a profession; and the only method by which a professional engineer can learn the practical part of his business is to "go through the shops" as a pupil. Difficult as it may be to define the relations between master and apprentice, the position in which an employer stands towards a pupil is less easy to determine. A busy manufacturing firm generally finds that pupils are on the whole a great nuisance in the works. The foremen have not, as a rule, complete control over them; and while the indolent pupils are continually playing the fool, the industrious ones are felt to be sucking the brains of their employers, who can really only utilize their talents by taking them on as members of their staff. This being so, it is not to be wondered that premiums of £500 for a three years' course are not uncommon. And if pupils still come at that price, it is not surprising that the employers are content to put up with some inconvenience.

But these large sums, together with the vague conditions which are generally made and the absence of any definite status, have tempted many ingenious people to trade upon the pupil system; and we are glad, for the sake of the public, that one of the worst cases of this kind, one which has for some years been known to the trade, was at last thoroughly exposed by the action which is reported in our Legal Intelligence. We do

Digitized by Google

not desire to dwell upon the disclosures, but propose to comment on the premium system; since this instance of grave abuse of it, instead of calling attention to the rather unsatisfactory state of the question, and to the directions in which improvement is possible, may be used as an argument against the general custom.

The opponents of the high premium say that it is a gross imposition to charge £300 to £500 merely for giving permission to a boy from school to prowl round among the benches and machines to pick up what he can. To this it may be answered, that the price of a thing is that which it will fetch. If a young man or his parents are desirous of doing the best that is possible to give him a good start, they will naturally turn to the leading firms; and these have three courses open to them: to reject all applications, as is done by some of the most important engineering establishments; to place the premium at such a figure that only a convenient number will be admitted; or to impose some other qualification, such as a certain proficiency in technical or theoretical knowledge. No one can grumble at the first, for there is no hope of hiding a trade secret from an inquisitive pupil; the last demands more trouble than most manufacturers are disposed to give, and we are thrown back upon the stiff premium.

To the definition of "the price of a thing," to which we have already alluded, must be added the warning, "*caveat emptor.*" Although an extremely high value attaches to the privilege of passing three years in the works of a large engineering firm, it must be remembered that a pupilage in the best firm in the country need not necessarily give a *cachet*, and the premium cannot strictly be regarded as an investment. We are not aware that a University degree is worth the proctor's fee to an engineer; but that is not any argument whatever against a University education, although it may cost nearly £1,000. On leaving the works, where he may or may not have made the best of his time, the young engineer will find himself in competition with those who have been turned out of some Technical College, with formulæ at their fingers' ends; while he, perhaps, has left one of his behind him at the factory—a finger end we mean, not a formula. It all depends on himself whether he can make better use of his practical experience than the other man can make of his theoretical knowledge. It is now generally conceded that at least a year or two in the lecture-room and laboratory should precede the entrance to the factory. The excellent technical education that is to be had to-day enables the term of pupilage to be reduced, and the premium naturally bears some proportion to the term. This reduction is alluded to in the admirable publication which has been recently issued by the Institution of Civil Engineers under the title of "Engineering Education in the British Dominions." But the payment of a premium should not be considered as a mere solatium for the trouble of having pupils about the works; and it would be quite possible to check larking, if not cigarette-smoking inside boilers, &c., by allowing pupils more frequently to do responsible work in which they would feel that they were of some use, and to make such occasions conditional on good behaviour. On the other hand, the "industrious apprentice" often finds that he is only allowed to learn, while wishing to be really taught. But a preliminary technical education will open his eyes to the directions in which he will learn most; and a little tact and a well-placed shilling or two besides his "footings" will put him in possession of all that his employer *cares that he should know.*

When a high premium is paid the employer should, we think, be more generous as to the range of information to which his pupils are allowed access. To learn engineering as a profession and to learn it as a science are two distinct matters, which differ only by the introduction of the commercial element. It is customary, we believe, to withhold from pupils all information as to cost of production, prime costs, &c. Unlike an articled architect, he very rarely sees a specification, estimate, or form of tender; and the whole commercial part of the business has to be learned afterwards, perhaps by bitter experience, which may cost far more than a dozen premiums. With a high premium, it becomes a duty on the part of the employer to give a pupil some chance of learning the elements of the commercial side of the business; and some facilities, even though they may take the form of inspection of prices of old and byegone jobs, or model dummy prime costs and specifications, should be granted. The other extreme is reached when pupils are taken on the understanding that they are going to learn engineering, but are kept in the office to do ordinary clerks' work. Fortunately, this is rare, the results probably leading to anything but a saving to the employers. We have heard of a case where pupils were not allowed to take any part whatever in the testing of dynamos.

So far we have not alluded specially to electrical engineering, since the greater includes the less. The ideal training is to go to a general engineering firm before taking up the electrical branch of the profession. Since only about half of those who turn to engineering after leaving school stick to it afterwards; and as it is difficult for a lad to make up his mind whether he will be an engineer or no, it must be still more difficult for him to decide upon a particular branch. The custom of paying £100 a year is more frequently to be found in electrical engineering, and one excellent result is that it allows a pupil to change his mind if he finds the work distasteful. The electrical engineer has, as a rule, much more occasion for the services of a technically trained staff than his purely mechanical *confrère*, and he will naturally make considerably more use of the most intelligent and industrious of his pupils. His responsibility towards them is therefore the greater; and we hope that the gross abuse of the pupil system which has been disclosed will be a warning to parents, and remind engineering firms that they should do something more for their pupils than pocket their fees and get as much useful work out of them as possible.

THE DETERMINATION OF CURRENTS IN ABSOLUTE ELECTRO-MAGNETIC MEASURE.

BY G. F. C. SEARLE, M.A.

(*Continued from page 716, Vol. XXVII.*)

§ 29. **Comparison of Galvanometer Constants.**—If we have a large standard coil whose dimensions have been carefully determined we may employ it to find the galvanometer constant of any other coil whose constant, either on account of the small size of the coil or the comparatively large space occupied by its windings, cannot be accurately calculated. Let G_1 be the galvanometer constant of the standard coil, G_2 that of the other coil. Place the two coils with their centres coincident, and their planes parallel to one another and to the magnetic meridian. Suspend at the common centre a very small magnet, with a mirror attached. The motion of the mirror is observed by a lamp and scale in the usual way. If currents are now sent round the two coils in opposite directions it will be possible, by properly adjusting the currents, to make the magnetic force at the centre due to the two currents vanish. When this is the case no deflection will be observed when the two currents are sent round the coils.

Let the coils be joined up as shown in Fig. 30, and let the resistance of the portion A G_1 B be R_1, while that of the portion

Digitized by Google

A G_2 B is R_2. Then the currents i_1 i_2, flowing through G_1 and G_2, are proportional to $1/R_1$ and $1/R_2$. If no deflection of the suspended mirror is produced, then $G_1 i_1 = G_2 i_2$, or $G_1/R_1 = G_2/R_2$. Thus, by the comparison of two resistances we can compare the two galvanometer constants. The difficulties to be overcome in making an accurate determination of the ratio R_1/R_2 are purely those connected with Ohm's law, and we shall not deal with them here.

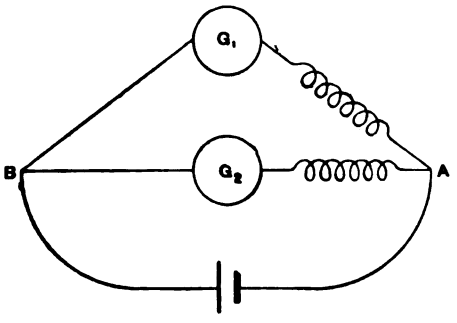

Fig. 30.

If suffixes 1 and 2 refer to the standard coil, and to the other coil respectively we have

$$\frac{G_1}{G_2} = \frac{R_1}{R_2} = \frac{n_1}{n_2}\,\frac{a_2}{a_1}\,\frac{1 + \frac{1}{3}\frac{h_1^2}{a_1^2} - \frac{1}{2}\frac{k_1^2}{a_1^2}}{1 + \frac{1}{3}\frac{h_2^2}{a_2^2} - \frac{1}{2}\frac{k_2^2}{a_2^2}}.$$

In some cases we wish to know the mean radius a_2 of the second coil in terms of that of the standard coil. We have then,

$$\frac{a_2}{a_1} = \frac{n_2 G_1}{n_1 G_2}\,\frac{1 + \frac{1}{3}\frac{h_2^2}{a_2^2} - \frac{1}{2}\frac{k_2^2}{a_2^2}}{1 + \frac{1}{3}\frac{h_1^2}{a_1^2} - \frac{1}{2}\frac{k_1^2}{a_1^2}}$$

If h_2, k_2 are small compared with a_2, then an approximate knowledge of h_2 k_2 and a_2 will enable us to obtain a very accurate value of a_2. The limit to the accuracy of this method is chiefly that imposed by the exactness of our knowledge of the relative resistances of the resistance coils used.

§ 30. **Electro-Magnetic Force on a Conductor.**—We proved in §20 that the mutual potential energy of any magnetic system and a magnetic shell was equal to the strength of the shell multiplied by the number of lines of induction due to the magnetic system, which would, if the shell were non-magnetic, pass through the shell in the opposite direction to those actually proceeding from the shell itself. Having proved the equivalence of a current and a magnetic shell, we can restate this result as follows:—The mutual potential energy (in ergs) of a closed current and any magnetic system is equal to the strength of the current multiplied by the number of lines of induction, which would, if the current were not flowing, pass through the circuit in the opposite direction to those actually due to the current. If we call N the number of lines through the circuit in the *same* direction as those due to the current itself, and i the strength of the current, then the mutual potential energy will be $-Ni$ ergs. The magnetic system may consist either of magnets or of currents in closed circuits.

From this result we can easily find the mechanical force acting upon the circuit in any direction. Let x (Fig. 31) be the distance of some point, P, rigidly connected with the circuit, from a fixed point, O, measured along the straight line O P Q. The circuit being kept parallel to itself, let it be moved so that P comes to Q where O Q $= x'$.

Let N be the number of lines of force due to the magnetic system passing through the circuit in the *same* direction as those due to the current itself, when the circuit is in the position defined by x. Let N′ be the number corresponding to x'. The values of the mutual potential energy of the magnetic system and the current in the two cases are $-Ni$ and $-N'i$ ergs. The potential energy has been increased by the motion from x to x' by the amount $-(N'-N)i$ ergs; in other words, this is the amount of work spent by external agencies in moving the circuit from x to x'. The force exerted by these agencies upon the circuit in the direction in which x increases is accordingly $-\frac{N'-N}{x'-x}i$ dynes. The mechanical force experienced by the circuit in consequence of the action of the magnetic system is equal and opposite to this, and is therefore $\frac{N'-N}{x'-x}i$ dynes. In the notation of the differential calculus we may write $X = i\,d\,N/d\,x$; X being measured in the direction in which x increases. Hence,

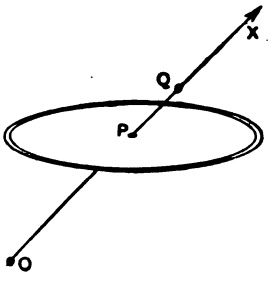

Fig. 31.

when N increases with x the circuit experiences a force tending to make x increase. Thus, if the circuit can move it will move so as to increase the value of N. Or we may say that the circuit tends to place itself so that the number of lines of induction passing through it is the greatest possible. If we bear this principle in mind we can at once understand all the forces experienced by currents when placed in a magnetic field.

§ 31. **Electro-magnetic Force on an Element.**—We will now investigate the force experienced by each portion of the conducting circuit when it is placed in a magnetic field. Take any circuit as in Fig. 32, having a sliding piece, P Q, sliding on two parallel wires one centimetre apart. Let a current i traverse the circuit in the direction indicated by the arrows. Now place the circuit in a magnetic field so that the lines of induction of the field near P Q are at right angles to the plane in which P Q moves, and in the direction going from the reader towards the paper. Let P Q be moved to P′ Q′ through a distance x. Then if the number of lines of induction due to the magnetic field per square centimetre of the plane in which P Q moves is **B**, the whole number of lines of induction which have been made to pass through the circuit in the same direction as those due to the current itself by the motion of P Q,* is $\mathbf{B}x$.

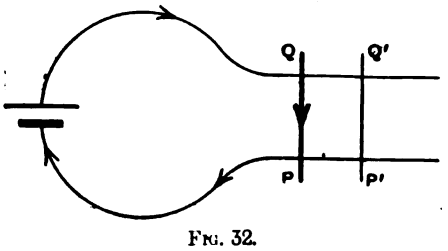

Fig. 32.

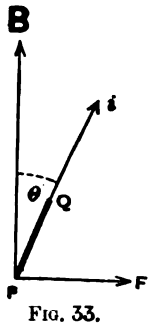

Fig. 33.

The work spent by external agencies upon the slider during its motion is therefore $-\mathbf{B}xi$ ergs. Hence the force experienced by the slider is in the direction P P′, so that if the slider is free to move it will move in that direction. The magnitude of the force on the unit length is $\mathbf{B}i$ dynes. We see also that the slider moves so as to increase the number of lines of induction passing through the circuit. If now the magnetic induction had not been at right angles to the wire at P Q, it is clear that only that component of the magnetic induction which is perpendicular to the wire can have any effect in changing the number of lines of induction through the circuit when the small portion P Q moves. Let θ be the angle between the direction of **B** and the direction of the current (Fig. 33). [P **B** and P F are in the plane of the paper, P Q is in a plane through P **B** at right angles to the paper, and its direction is *from* the reader.] Then the magnetic

Digitized by Google

induction perpendicular to the current P Q is $\mathbf{B} \sin \theta$. Let the two wires upon which P Q slides be placed so as to be at right angles to the plane containing the directions of **B** and P Q. The variation in the number of lines through the circuit due to the motion of P Q will then be the most rapid possible, and consequently the direction of the electro-magnetic force experienced by P Q will be along these wires, *i.e.*, at right angles to the plane of **B** and P Q. The resultant force experienced by the sliding piece is therefore $F = \mathbf{B} i \sin \theta$ dynes per centimetre of its length at right angles to the planes of **B** and i. The consideration of the first case will show that the direction of F is along P F, and is related to the directions of **B** and i in the following way. If a right-handed screw is placed with its axis along the direction of the force, then a rotation in the direction from i to **B** makes the screw advance in the direction of the force. Another way of remembering the direction of the force is the following. Imagine an observer placed so that the current runs from his feet to his head. Let him then turn round till his right hand points in the direction of the magnetic induction. The force acting on the conductor is then such as to make him move forwards. This rule is easily remembered, and is of great assistance in finding the direction of the force experienced by the current. The quantity $\mathbf{B} i \sin \theta$ is the area of the parallelogram formed on **B** and i as sides; it is the vector product of the two vectors i and **B**.

An important point arises as to the determinateness of the action experienced by an element of the current when placed in a magnetic field. If we examine the process described at the beginning of this paragraph, we see that it consists not only in increasing the area of the circuit by the area PQQ'P', thus increasing the number of lines of force due to the magnetic field which pass through the circuit, but also in producing the extensions of the current represented by PP' and QQ'. Unless we are prepared to affirm that the creation of a current in the two portions PP' and QQ' while they are under the influence of the magnetic field involves no expenditure of energy, we are not entitled to state that the force experienced by the element ds is the vector product of $i\,ds$ and **B**. If we move the circuit so that we introduce no new parts, then this difficulty disappears, and the force experienced by the circuit as a whole will be the same as if forces represented by $\mathbf{B} i\,ds \sin \theta$ were applied to each element of the circuit at right angles to the plane of **B** and $i\,ds$. If we wish to increase the area of the circuit by a given amount, we can either make PQ small and PP' comparatively large, or we can make PP' small and PQ comparatively large. When PQ is small so that it approximates to a true "element," the uncertainty arising from the extensions PP', QQ' will be large, while when PQ is large the uncertainty will be very small since PP' is very small. But when PQ is large compared to PP', it may be regarded as having made a considerable step towards its development into a closed circuit. This illustration helps us to understand the statement that although we can assert positively that the action experienced by a closed circuit in any magnetic field is the same as if forces $\mathbf{B} i\,ds \sin \theta$ were applied to each of the elements of the circuit, still the action experienced by each element is really indeterminate. We shall never fall into any error in taking $\mathbf{B} i\,ds \sin \theta$ as the force experienced by an element provided that we extend our calculations to the *whole* of the circuit. This limitation is really no hardship, since all circuits in nature are closed.

(To be continued.)

THE COLOGNE AND DÜSSELDORF MUNICIPAL CENTRAL LIGHTING STATIONS.

(FROM OUR GERMAN CORRESPONDENT.)

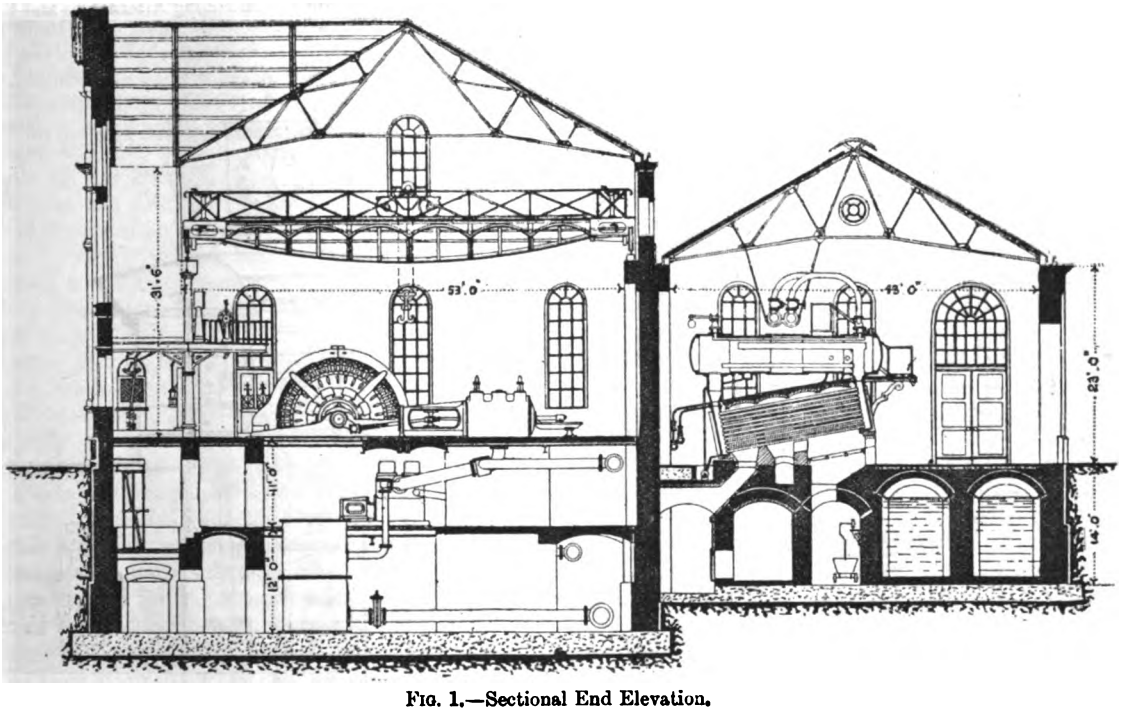

FIG. 1.—Sectional End Elevation.

The Cologne central station, of which the accompanying illustration (Fig. 1) shows a section, is situated at the side of the Municipal Gas and Waterworks, and is, in fact, under the same administration. This is a good plan—saving, as it does, the expenses of a separate administrative staff, and rendering possible the supply of steam to the engines of the electric central station from the boilers of the Waterworks during the hours of light load.

The boiler-house, which is 152ft. long and 43ft. across, contains five pairs of Steinmüller boilers, each of 1,650 square feet heating surface, and working at a pressure of 114lbs. per square inch. Below each ashpit there is a shoot running to a tunnel, in which are small trucks, which, after being filled with the ashes, may be run out into the yard. The engine-room is the same length, but 53ft. broad and considerably higher. It contains, at present, two 600 H.P. Sulzer compound condensing engines, and one 125 H.P. Sulzer engine, also compound, and provided with a condenser. These engines (Fig. 2), the shafts of which

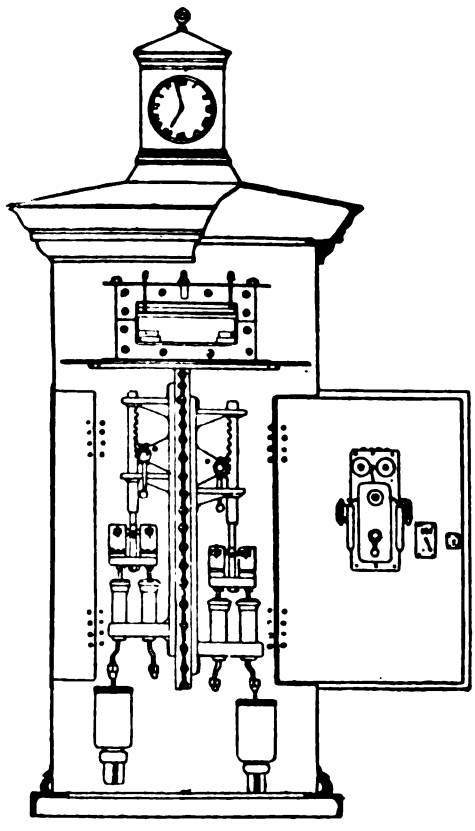

FIG. 4.—"Disconnecting Column."

Digitized by Google

carry the hubs of the magnet-wheel of the alternators, run at 85 revolutions, requiring, therefore, 72-pole alternators to give 50 complete cycles per second. The spindles of the magnet-wheels also carry the ring armature of an eight-poled exciter, the field-magnets of which are attached to the stationary armature of the alternator by means of four cast-iron arms. These arms and the spindle are, in fact, the only cast-iron parts of these dynamos, if we leave out of view the large ring-shaped frame to which the armature coils of the alternator are attached in the well-known Zipernowsky manner. The field-magnets of the exciters, although ring-shaped and containing eight radial polar projections, are wholly built up of iron sheets, half a millimetre (20 mils.) thick, and of half-ring shape, the polar projections being cut out by means of boring and slotting machines, after the whole of the field has been first screwed and then riveted together. The weight of iron in the exciter armature is nearly 1 ton 2cwt. for the 600 H.P. dynamo, and about 14cwt. for the 125 H.P. dynamo. The weights of copper are respectively about 6½cwt. and 4½cwt. upon the armatures, and 13cwt. and 9½cwt. upon the field-magnets of the exciters; these are shunt-wound for the 125 H.P. dynamo and compound for the large dynamos. In spite of the low speed these dynamos have an electrical efficiency of 93 and 89 per cent. respectively, and a commercial efficiency of 90 and 85 per cent., including the exciter. In Fig 1 a 25-ton travelling crane is also shown. This crane can travel through the whole length of the engine-room. The magnet-wheel of the alternator and the armature of the exciter, which is attached to the former, can be moved laterally so far that the parts of each may be easily got at, this lateral movement being made by means of sliding bars and a hand-wheel.

I now come to the description of that part of the central station which distinguishes it from all others which have been erected so far. The extreme simplicity of handling all these dynamos, combined with the want of all visible connections which could annoy the mind of the mechanical engineer, are certainly a decided advance; this central station is not a labyrinth of hundreds of bare or insulated conductors, but rather a simple looking machine station, the control and regulation of which is effected by a simple mechanism moving a couple of levers. These lever mechanisms, of which Fig. 3 is an elevation, are due to Herr Carl Coerper, the managing director of the Helios Company of Cologne, which erected this station. Two such arrangements have been exhibited at Frankfort.

The method of introducing one alternator into the circuit to work in parallel with one already running is as follows:—Lifting the handle of the bolt (Fig. 3), we move the lever *d* until the bolt fits into the first hole. We have in this way completed the field-circuit of an exciter. We now proceed to regulate the excitation by slowly moving the second lever *c*. The field having attained a suitable degree of excitation, we close the main circuit of the exciter, *i.e.*, the field of the alternator, by moving lever *d* to the last notch of the sector. Then by taking resistance out of the field circuit of the alternator by moving lever *b*, we excite it to its normal pressure. So far no damage could have been done if any of the levers had been handled wrongly or in the wrong order. To avoid any damage being done by an inattentive man, Herr Coerper has employed a locking device which renders it impossible to introduce the dynamo directly into the lamp circuit. By moving lever *a* to the first slot in its disc, we complete the circuit of the load of resistances, and we must now turn the wheel *e* before we can go on with our lever. By doing so we introduce more and more resistance, and only now can we move *a* to the next position, when this resistance and the lamp-circuit are in parallel. We then have to turn *e* backwards, and after having wholly taken out the resistance load, we move the lever to its last position, when the dynamos will be working in parallel with the others upon the town circuit.

I have now to mention the fourteen "disconnecting columns," by means of which any part of the whole network may be disconnected, thus allowing new portions of cable to be joined or new house junctions to be made, which is necessary as there is no secondary network at all in this town. Fig. 4 shows one of these columns designed for use at Amsterdam, containing four mercury switches and cable ends, an alternating current clock, and a small telephone station, which allows of communication between these "disconnecting columns" and the central station. For this purpose about three and a-half miles of telephone cable have been put down with the eleven miles of concentric cable. The columns adopted at Cologne are minus the clock.

The cables are placed in wooden troughs in which they are supported by iron hooks, the troughs are filled with molten asphalt and then covered with a layer of bricks and sand. The cables, which were furnished by the Société d'Exploitation des Câbles Électriques (Système Berthoud, Borel et Cie), of Cortaillod, Switzerland, are moreover protected by lead and iron sheathing. Each length of 200 to 300 yards has been tested at double the working pressure, namely, to 5,000 volts, between the two conductors, and between the exterior conductor and the lead cover. The insulation resistance of the whole network, measured with 100 volts, and a mirror galvanometer, was found to be 1,000 megohms per mile.

The supply network is calculated for a maximum output of 20,000 16 candle-power lamps, burning simultaneously. The first portion of the plant, comprising two 500-600 H.P. dynamos, and one of 125 H.P., will, however, soon be too small. Since the opening of the station at the commencement of September, 200 house connections have been made, and about 100 transformers have been installed, the total primary current being at present about 45 amperes, equal to about 1,600 lamps burning, and nearly 6,000 installed; and this number will certainly be greatly increased as Christmas approaches.

The transformers (Fig. 5) which contain three secondary terminals with a potential difference of 36 volts between an exterior and the middle terminal, or 72 volts between the two exterior ones, have been built for this low pressure to avoid great losses in the resistances for arc lamps, the Helios Company having succeeded in turning out an alternate current arc lamp giving a white and steady light, and running off 36 volts, including resistance. For this reason the three-wire system is employed in most cases of house-wiring for the arc lamp leads, two wires being in use for the incandescent lamps. The terminals of the transformer are put out of the reach of private persons by means of a metal case, not shown in the figure, which represents a 10-kilowatt transformer. This size is generally used for large houses, or cases where two or three small houses are joined to one transformer.

The electric meter (Fig. 6) adopted is the Bláthy. The shunt field, on account of its high self-induction, reaches maximum magnetisation about a quarter of a period after the main field, and when at zero magnetisation produces powerful eddy currents in a rotating aluminium disc. This eddy current moves in such a direction that it is attracted by the main field, which, at this time, possesses maximum magnetisation. When, on the other hand, the main field equals zero, it produces an eddy current in another part of the disc, which is displaced from the point where the shunt field's eddy currents are generated by a quarter of the disc's circumference, the main field eddy current being besides in such a direction that repulsion takes place between it and the shunt field, which is very strong at this instant. A continuous rotation, therefore, takes place. The committee which tested the Bláthy meter about one year ago at Frankfort found that it started with one 100-volt 16 candle-power lamp, that is, with 0·5 ampere, and that its rotation continued to be proportional within three per cent. throughout its range, that is, from less than one ampere up to 100.

As to the central station's rules for house-wiring, the principal points are the following:—The working pressure is 72 volts, and the wiring has to be carried out on the assumption of one ampere being required for each 16 candle-power lamp, and of a loss of one volt from the transformer terminals to the last lamp, when all the lamps installed are burning. This allows 20 candle-power lamps to be inserted instead of 16 candle-power lamps, without passing the limit of one volt loss. Of course, this results in somewhat stout leads, and it is not necessary to limit the maximum current density to two amperes per square millimetre (1,300 amperes per square inch) as for long leads, this load can never be attained with a loss of only one volt. The insulation resistance of the whole installation

Digitized by Google

has to be 1/C of a megohm, C standing for the current required by the respective installation. No wire is to be placed below a ceiling or a floor, unless lead-covered, and iron-armoured concentric cables are employed for this purpose. The smallest safety fuse must melt at six amperes, and all fuses have to be double poled. For testing the installation before connection to the network the consumer has to pay about 1s. per lamp up to 50 lamps; from 50 up to 500 lamps the sum decreases rapidly, since for 500 lamps £8. 6s. (166 marks) has to be paid. Transformers and meters, as well as the short end of primary cable from the network into the cellar of the consumer's house, are the property of the municipality. For the meter there is the same annual payment as for gas meters, that is 10s. to 20s. For every lamp installed, be it arc or incandescent lamp, the consumer has to guarantee a mean annual utilisation of 300 hours. The price charged is 8 pfennigs per 100 watt-hours (9½d. per B.T.U.). To large consumers there is, of course, a rebate. The largest consumer, except the theatre, which is not yet connected to the station, will perhaps be the old signalling and telephone lines. The sub-stations, of which the largest contains 140 Tudor accumulators with a discharge current of 1,000 amperes, contain also the regulating devices by means of which cells are disconnected or joined in order to keep the volts constant. From the sub-stations, the accumulators at which will be kept in order by the manufacturing firm of Hagen for ten years, the feeders and distributing leads are laid upon the three-wire system. The network is calculated for 25,000 lamps, and there are already demands for the equivalent of 15,000 16 candle-power lamps, of which about 10,000 are already installed.

The consumer has to bear the costs of connecting-up unless he has subscribed by November 1st for three years, in which case the municipality will bear the cost. The consumers pay monthly for a meter up to 15 lamps of 16 candle-power, one shilling; for a 30 lamp meter, 1s. 6d.; for a 60 lamp meter, 2s. 3d.; for a 100 lamp meter, 3s., and for every additional 100 lamps one shilling more. For 100 watt-hours the charge is 9 pfennigs (11d. per B.T.U.). If, however, the consumer

"Gürzenich," where over 800 lamps are to be installed by the Helios Company.

The following are some additional particulars with regard to the Düsseldorf municipal central station, which was opened on October 24th, and of which you had a brief account in your issue of October 30th. The whole work, which was carried out by Messrs. Schuckert, of Nuremburg, comprises a central station and three sub-stations. The station itself, situated near the municipal gasworks, and covering an area of 10,760 square feet, comprises two engines of 300 effective H.P., running at 90 revolutions and coupled direct to disc armature dynamos. A third similar machine will soon follow. The engines are horizontal tandem machines, working with a pressure of 114lbs. per sq. in., and were constructed by the Sächsische Maschinenfabrik, of Chemnitz. The disc-armature dynamos give 1,000 amperes at 350 volts. The discs have a diameter of 10 feet, and have a peripheral velocity of nearly 2,600 feet per minute. The magnetic field is a cast-iron shell, provided with 28 polar projections. The diameter of the commutator is 6½ feet. Steam is furnished by two water-tube boilers of 1,650 square feet heating surface, constructed by the Hohenzollern Company, of Düsseldorf; a third similar boiler forms a reserve. From the station there are six feeders to the sub-stations, two for each, whose mean lengths are about 1½ miles. The feeders as well as the distributing mains, which have a total length of 88 miles, have been furnished by Messrs. Felten and Guilleaume, of Mülheim, are laid side by side in trenches about 3ft. 3in. deep, which are filled in with a layer of yellow sand and then protected with iron plates. Between the central station and the sub-stations there are

POLYPHASE CURRENT MOTORS.

The question of polyphase currents and rotary field motors, says our Paris correspondent, being the order of the day, although but few persons in France have up to the present studied it, M. E. Hospitalier read a lengthy Paper on the subject on Thursday last week before the Société Internationale des Électriciens, with a view of saving those who are interested in the matter the labour of personal investigation. M. Hospitalier described with his customary clearness the methods of generating and utilising polyphase currents, and explained their advantages and disadvantages. The polyphase currents generally used were, he said, either two-phase, lagging a quarter of a period, or three-phase, lagging a third of a period. In the first case three wires at least were necessary, one being larger than the other two; in the second case, three wires were also required, but they were all of the same diameter. At any instant the algebraical sum of the ordinates of the three sine curves was zero, and consequently any one of the currents might be considered to be the sum of the other two.

Digitized by Google

Production.—To generate a three-phase current it was only necessary to take three coils each ⅓rd of a period in advance of the other, and revolve them in a uniform magnetic field. M. Hospitalier then described the Lauffen generator. The three groups of coils could, he remarked, be arranged in two different ways, viz, either in a star Y or in a triangle Δ. The star grouping had been adopted for reasons of safety. For experimental purposes it was possible to make a three-phaser by merely taking a Gramme alternator, with revolving field-magnets, and suitably connecting up the fixed armature coils.

Transformation and Transmission.—M. Hospitalier next described the Lauffen-Frankfort three-core transformers, intended to step the volts up from 50 to 15,000 at Lauffen, and step them down in the same ratio at Frankfort. He laid stress on the advantage of the star method of grouping the coils. The common junction of the three coils was, he pointed out, always at zero potential. It could, therefore, be earthed; and, in fact, in the case of the Lauffen-Frankfort transmission, the central point of the generator coils, of the high-pressure transformer coils, and of the low-pressure transformer coils, were all earthed with great care. A short circuit between primary and secondary would, therefore, cause the fuses to go immediately.

Utilisation.—Polyphase currents, in M. Hospitalier's opinion, lend themselves more readily than ordinary alternating currents to applications of a calorific, mechanical, or chemical nature. To bring out the peculiarities of three-phase currents, M. Hospitalier arranged three glow-lamps star fashion, the three external terminals being joined to three wires coming from a three-phaser. The equal brilliancy of each of the three lamps showed that if the currents in the lamps were not equal at any instant, their effective luminous intensities were. Polyphase current motors were, the lecturer said, based on the employment of rotary field generated by three currents sent through three circuits. The resultant field is constant, and revolves at a uniform speed. If a closed circuit is placed within such a field, alternating currents will be generated, and it will rotate in the same direction and at nearly the same speed as the field. As an illustration three flat coils, placed 120deg. in advance of each other, and having a magnetic needle at the centre, were shown. When a three-phase current was passed through the coils the needle rapidly revolved, and quickly changed direction when the current in two of the coils was reversed. The Brown motor was explained in detail, a little motor on this principle being exhibited and worked. The field magnet was a Gramme ring armature, connected at three points to wires coming from a three-phaser. In the centre of the Gramme ring was an armature, consisting of insulated copper bars buried in a laminated iron cylinder, all the bars being joined in parallel by two bronze discs keyed to the spindle. The rapidity with which the direction of rotation was changed when the direction of the current in two of the coils was reversed, was very remarkable.

M. Hospitalier then dwelt on the apparatus shown at Frankfort by Herr Schuckert, and which the lecturer christened "Continuous-current, alternate-current, three-phase motor-generator." This machine consists of a Gramme dynamo, on the spindle of which (at the opposite end to the commutator) there are three rings joined to three points of the armature 120deg. apart. This combination may be said to have six different functions according as it is supplied with mechanical energy, a continuous current, or a three-phase current, since if we give it one of these components it turns out the other two. It was a machine of this kind, built by M. Hillairet, that M. Hospitalier made use of for his experiments. A continuous current was supplied it, and it gave out mechanical energy and three-phase currents.

In conclusion, M. Hospitalier spoke of two-phase currents, of the system employed by Herr Schuckert for transforming and transmitting two-phase currents using three wires, and of the future of polyphase currents. Three-phase currents, he said, allow us to employ motors, having no collector, no commutator, no brushes, and possessing a maximum torque on starting. These advantages were particularly interesting in view of their possible application to mining machinery. The necessity for three wires rendered the application of the three-phase system to tramways out of the question. On the other hand, important researches were being carried out at that moment to obtain the same results with two wires, but the idea was not as yet sufficiently matured to say more at present.

LEAD "GALVANISING."

"Galvanising" as ordinarily understood is a somewhat misleading term. It has for all that a substratum of fact, having been evolved from a consideration of the electrical relations of zinc and iron. (The best process of galvanising iron is, indeed, to deposit a thin coating of tin electrically, before immersion in the melted zinc, but it is seldom used.) When applied to a method of coating iron and steel with lead it becomes remarkable rather as illustrating the growth of a technical word than as being particularly apposite. As many of our readers may be aware, there have lately sprung into existence several processes for protecting iron and steel by means of a covering of lead, instead of zinc, tin, or terne, some at least of which promise to oust the older methods from a good many of their applications.

One of these lead-covering processes is being brought out by an English syndicate working on lines which are said to have been successfully followed in America for the last three or four years. A fair-sized experimental plant has been set up at Messrs. Westwood and Company's works at Millwall, sufficient to show something of the capabilities of the process even to those more accustomed to judge of the probable success of a new undertaking from the results it gives when conducted on a small manufacturing scale, than from those obtained by a properly devised series of laboratory tests. The method itself may be described quite briefly: The actual coating of articles of iron or steel is effected much as in common galvanising, save that the bath consists of lead instead of zinc. It is in the preparation of the sheets, &c., before coating that the individuality of the process consists. In place of the ordinary pickling bath for removing scale and dirt, one is used composed of a mixture of hydrochloric and hydrofluoric acids, 10 per cent. of the former and 1 per cent. of the latter being employed. In this bath the removal of the scale is hastened by making the articles to be treated the anode of a weak current passing through the tank. On the strength of this arrangement the process had the term "electro" tacked to its name; but the intrinsic absurdity of such an affix having become plain to its proprietors the offending epithet is now in process of suppression. Although, perhaps, this is as well, yet it may be noted that a substantial advantage appears to accrue from the use of a weak current under these conditions, a saving in time of about one-third of that otherwise requisite being attained; we draw attention to this point because we consider that in many industries a similar utilisation of the selective and transferring powers of electrolysis might well be made, provided the adapters do not kill the enterprise by describing the use of electricity as essential instead of purely secondary, and thus ranking their device with the many quack processes which have been thus dubbed.

After being pickled in the acid bath above mentioned the articles to be coated are transferred to a tank of lime-water to remove adhering acid, and then passed into one consisting of a solution of the chlorides of tin and zinc made by dissolving equal weights of the two metals in hydrochloric acid to the saturation of the latter, and thence to the bath of melted lead aforesaid.

The process as thus conducted seems to be efficient, the covering of even complicated surfaces being readily effected; the lead adheres to the underlying metal with considerable tenacity, a property which may be ascribed to the very careful and thorough cleansing the latter undergoes before immersion in the former. The precise chemical effect of the hydrofluoric acid in the first bath is far from clear; but it is reasonable to suppose that the zinc chloride and stannous chloride constituting the third, act, the one by removing any trace of oxide that may still adhere after the preliminary pickling, and the other by

Digitized by Google

preserving the chemically clean iron from possible oxidation at a later stage. When once the adhesion of the lead to the iron has been secured, the softness and ductility of lead will allow considerable deformation of the underlying metal before fracture of the coating occurs. In this respect lead presents a great contrast to zinc, and might replace it for many purposes if it were not that, being electro-negative to iron, it tends to hasten the attack of the latter by most of the corrosive agencies to which the coated metal is exposed, under such conditions as permit both lead and iron to be in contact with an electrolyte. The preservation of the lead coating in its integrity would prevent corrosion of this character taking place; and considering the perfection of the adhesion of the lead to the iron the chance of removal by cracking or scaling is remote. On the other hand, the extreme softness of lead must cause it to be readily pierced and even stripped by chafing against any moderately hard substance; and from the moment when a portion of the iron has been laid bare, the process of corrosion will proceed with greater rapidity at the particular spot exposed than would have been the case had the metal been wholly unprotected. It is true that it may be found that the corrosion may be confined to the portion of the metal exposed, and be of less complete and injurious character than that which occurs in the case of ordinary tin plate. This is, however, an assumption that can only be proved or disproved by experiment. We insist somewhat strongly upon this point, inasmuch as should the objection we have indicated be overruled by actual trial, or provided for by some modification of the present method, the process will supply many of the needs of the electrical engineer. Among the applications which may be quoted are the coating of telegraph posts, the protection of iron and steel wire, and the formation of lead-lined tanks for electrolytic operations. The covering of wire is an application of special interest, on account of the absence of any tendency on the part of the lead coating to reduce the tensile strength in the manner peculiar to galvanising. A smaller but not uninteresting use to which lead coating may be put is the protection of staples, large numbers of which are at present galvanised; the act of driving in a galvanised iron staple is very liable to chip its coating, a result little to be feared when its covering is lead: indeed, lead-covered staples are said to endure the test of being opened out flat without damage to the coating or fracture of the iron itself. The method, as it stands, appears promising, and upon the tendency of partially stripped articles to suffer severe corrosion being avoided or mitigated, should find many useful applications.

ON THE DISCHARGE OF ELECTRICITY THROUGH EXHAUSTED TUBES WITHOUT ELECTRODES.*

BY J. J. THOMSON, M.A., F.R.S.

(Continued from page 15.)

Action of a Magnet on the Discharge.

The discharges which take place in these tubes and bulbs are produced by periodic currents, so that the discharges themselves are periodic, and the luminosity is produced by currents passing in opposite directions. As this is the case, it seemed possible that the uniformity of the luminosity seen in the discharge was due to the superposition of two stratified discharges in opposite directions, the places of maximum luminosity in the one fitting into those of minimum luminosity in the other. Since these discharges are in opposite directions, they will be pushed opposite ways when a magnetic force acts at right angles to them, the discharges in opposite directions can thus be separated by the application of a magnetic force and examined separately. In the experiment which was tried with this object, a square tube was used placed outside the primary, the tube at one or two places being blown out into a bulb so as to allow of the wider separation of the constituent discharges. When one of these bulbs was placed in a magnetic field where the force was at right angles to the discharge, the luminous discharge through the bulb was divided into two portions which were driven to opposite sides of the bulb; each of these portions was of uniform luminosity and exhibited no trace of striation. It was noticed, however, in making this experiment that the discharge seemed to have much greater difficulty in passing through the tube when the electro-magnet was on than when it was off. This observation was followed up by several other experiments, and it was found that the discharge is retarded in a most remarkable way by a magnetic force acting at right angles to the line of discharge. This effect is most strikingly shown when the discharge passes as a ring through a spherical bulb. If such a bulb is placed near a strong electro-magnet, it is easy to adjust the length of spark so that when the magnet is off a brilliant discharge passes through the bulb, while when the magnet is on no discharge at all can be detected. The action is very striking, and the explanation of it which seems to fit in best with the phenomena I have observed is that the discharge through the rarefied gas does not rise to its full intensity suddenly, but as it were feels its way. The gas first breaks down along the line where the electromotive intensity is a maximum, and a small discharge takes place along this line. This discharge produces a supply of dissociated molecules along which subsequent discharges can pass with greater ease. Thus under the action of these electric forces the gas is in a state of unstable equilibrium, since as soon as any small discharge passes through it the gas becomes electrically weaker and less able to resist subsequent discharges. When the gas is in a magnetic field, the magnetic force acting on the discharge produces a mechanical force which displaces the molecules taking part in the discharge from the line of maximum electric intensity, and thus subsequent discharges do not find it any easier to pass along this line in consequence of the passage of the previous one. There will not, therefore, be the same instability in this case as in the one where no magnetic force acted upon the gas. A confirmation of this view is, I think, afforded by the appearance presented by the discharge when the intensity of the magnetic field is reduced, so that the discharge just, but only just, passes when the magnetic field is on. In this case the discharge, instead of passing as a steady fixed ring, flickers about the tube in a very undecided way.

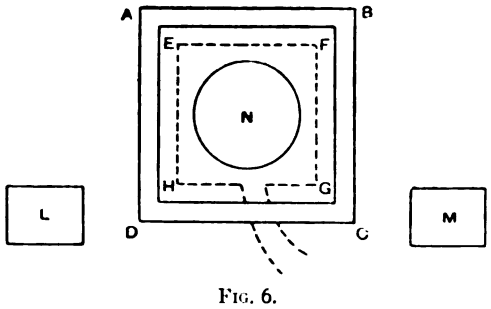

FIG. 6.

If the strength of the magnetic field is reduced still further, so that the discharge passes with some ease, the bright ring which, when no magnetic force is acting, is in one plane, is changed into a luminous band situated between two planes which intersect along a diameter of the bulb at right angles to the magnetic force. These planes are inclined at a considerable angle, one being above and the other below the plane of the undisturbed ring. This displacement of the ring by the magnetic force shows that it consists of currents circulating tangentially round the ring.

This action of a magnet on a discharge flowing at right angles to its lines of force is not, however, the only remarkable effect produced by a magnet on the discharge. When the lines of magnetic force are along the line of discharge, the action of the magnet is to facilitate the discharge and not to retard it as in the former case. The first indication of this was observed when the jars were connected, as in (*a*) in Fig. 1. The earth-connection being removed, in this case there is a glow from the glass into the bulb, due to the redistribution of the electricity induced on the glass by the primary when it is at a high potential before the spark passes. If the primary is connected to earth by a circuit with an air-break in it, the intensity of the glow may be altered at will by adjusting the length of the air-break; when the air-space is very small there is no glow; when it is long the glow is bright. The bulb in which the discharge was to take place was placed on a piece of ebonite over the pole of an electro-magnet, and the air-space in the earth-connection of the primary was adjusted so that when the magnet was off no glow was observed in the tube. When the magnet was on, however, a glow radiating in the direction of the lines of magnetic force was produced, which lasted as long as the magnet was on, and died away rapidly, but not instantaneously, when the magnet was taken off. In this case the discharge seems to be much easier along the lines of magnetic force.

The following experiment shows that this effect is not confined to the glow discharge, but is also operative when the discharge passes entirely through the gas. A square tube A B C D (Fig. 6) is placed outside the primary E F G H, the lower part of the discharge tube C D being situated between the poles L M of an electro-magnet. By altering the length of spark of the Wimshurst machine,

* Abstract from the *Phil. Mag.* October, 1891.

Digitized by Google

the electromotive intensity acting on the secondary can be so adjusted that no discharge passes round the tube A B C D when the magnet is off, whilst a bright discharge occurs as long as the magnet is on. The two effects of the magnet on the discharge, viz., the stoppage of the discharge across the lines of magnetic force, and its acceleration along them, may be prettily illustrated by placing in this experiment an exhausted bulb N inside the primary; then the spark length can be adjusted so that when the magnet is off the discharge passes in the bulb and not in the square tube, while when the magnet is on the discharge passes in the square tube, and not in the bulb.

The experiments on the effect of the magnetic field on the discharge were tried with air, carbonic acid, and oxygen, but I could not detect any difference in the behaviour of the gases.

The explanation of the longitudinal effect of magnetic force seems more obscure than that of the transverse effect; it is possible, however, that both may be due to the same cause, for if the feeble discharge which we suppose precedes the main discharge branches away at all from the line of main discharge the action of the magnetic force when it is along the discharge will tend to bring these branches into the main line of discharge; and thus there will be a greater supply of dissociated molecules along the main line of discharge, and therefore an easier path for the subsequent discharges when the magnetic force is acting than when it is absent.

It is perhaps not necessary to assume that the mechanical action of the magnetic force is on a small discharge preceding the main one; the action of the magnetic force on the chain of polarised molecules which are formed before the discharge passes might produce an effect equivalent to that which we have supposed was produced on an actual discharge.

The chain of polarised molecules would be affected in the following way:—The magnetic field due to the electro-magnet consists of tubes of electrostatic induction moving about; these tubes, as well as the direction in which they are moving, are at right angles to the lines of magnetic force. The short tubes of electrostatic induction which join the atoms in the molecules of the gas will, under the influence of the electric forces, set themselves parallel to the direction of the electromotive intensity at each point.

Thus, when the magnetic force is at right angles to the line of discharge, tubes of electrostatic induction parallel to those in the molecules will be moving about in the field; and since parallel tubes exert attraction and repulsion on each other, the molecular tubes will be knocked about, and their efforts to form closed chains made much more difficult by the action of the magnet. On the other hand, when the lines of magnetic force are parallel to the discharge, the moving tubes are at right angles to those in the molecules, and will not disturb them in the attempt to form chains along the line of magnetic force, they will in fact assist them in doing so by preventing all attempts in directions across the lines of force.

Prof. G. F. Fitzgerald has suggested to me in conversation that this action of a magnet on the discharge might be the cause of the "streamers" which are observed in the aurora; the rare air being electrically weaker along the lines of magnetic force than at right angles to them will cause the discharge in the direction of those lines to be the brightest.

Discharge through Different Gases.

I have examined the discharge through air, carbonic acid, hydrogen, oxygen, coal gas, and acetylene. As I have already mentioned, at the highest pressures at which the discharge passes through air, the discharge is reddish, and gets brighter and whiter at lower pressures. If the discharge is examined through a spectroscope the lines in the spectrum coincide with those obtained by sparking through air in the ordinary way with a jar in the circuit. The relative brightness of the lines in the spectrum of the discharge without electrodes varies very much with the pressure of the gas and the length of spark in the jar circuit. With a long spark in this circuit, and the pressure such as to give a bright white discharge, the spectrum is very much like that of the ordinary jar-discharge in air. When, however, the pressure is so low that the discharge passes with difficulty, a few lines in the spectrum shine out very brightly, while others become faint, so faint indeed sometimes that if the air-spectrum were not thrown into the field of view of the spectroscope at the same time they might pass unnoticed. Three lines which are very persistent, the first a citron-green, the second a more refrangible green, and the third a blue, I am inclined to think must be due to mercury vapour from the pump.

I am indebted to Prof. Liveing for the loan of a very fine direct-vision spectroscope, and to him and Mr. Robinson, of the Cambridge Chemical Laboratory, for valuable advice in the attempts which I made to photograph the spectra of some phosphorescent glow mentioned below.

I should like to call attention to the advantages for spectroscopic purposes which attend this method of producing the discharge: it is easily done, either by an ordinary electrical machine or an induction coil. An intensely bright discharge is got, and there is no danger of complication arising from the spectrum of the gas getting mixed with that of the electrodes.

Discharge in Oxygen.

By far the most remarkable appearance is presented when the discharge passes through oxygen, for in this gas the bright discharge is succeeded by a phosphorescent glow which lasts for a considerable time; indeed, with a strong discharge it may remain visible for more than a minute. When the discharges succeed one another pretty rapidly, the phosphorescence is so strong that it hides the successive bright discharges, and the tube seems permanently full of a bright yellow fog. We can thus by the use of this gas convert the intermittent light given by the bright discharge into a continuous one.

Perhaps the most striking way of showing this phosphorescence is to use a long tube, about a metre long and 6 or 7 centimetres in diameter, with a bulb blown in the middle, the primary coil being twisted round this bulb. Then, when the sparks pass between the jars, a bright ring-discharge passed through the bulb, from which, as if shot out from the ring, the phosphorescent glow travels in both directions along the tube, moving slowly enough for its motion to be followed by the eye. It cannot, therefore, be produced by the direct action of the light from the spark on the gas in the tube, for if it were, the glow would travel with the velocity of light. It is necessary to mention this point, for the light from these discharges has great powers of producing phosphorescence.

The glow seems to consist of gas which has been in the path of the discharge, and whose molecules have been split up by it and projected from the line of discharge. This gas, which, when projected, is in a peculiar state, by a process of chemical combination gradually returns to its original condition, and it is while it is in this state of transition from its new condition to the old that it phosphoresces. If this is the case we should expect that the period of phosphorescence would be shortened by raising the temperature. On trying the experiment I found that this took place to a very marked extent. A discharge-bulb filled with oxygen at a low pressure was placed over a Bunsen burner; before the bulb got hot each bright discharge was succeeded by a bright after-glow, but as the bulb got hotter and hotter the glow became fainter and fainter, and at last ceased to be visible, though the bright ring was still produced at each discharge of the jar. When the Bunsen was taken away, and the bulb allowed to cool, the glow reappeared.

The spectrum of the afterglow is a continuous spectrum, in which I could not detect the superposition of any bright lines. The only gas besides oxygen in which I have been able to detect any after-glow is air, though in this case the range of pressure within which it is exhibited is exceedingly small; indeed, it is often by no means an easy matter to get a bulb filled with air into the state in which it shows the glow. The spectrum of the air-glow showed bright lines; I thought myself that I could see a very faint continuous spectrum as well. Some friends, however, who were kind enough to examine the spectrum, though they could see the bright lines clearly enough, were of opinion that there was nothing else visible. I endeavoured to photograph it, but without success, so that the existence of a continuous spectrum for this glow must be considered doubtful.

When the discharge passes through acetylene, the first two or three discharges are a bright apple-green, the subsequent ones, however, are white, and as the green discharge does not reappear we must conclude that the acetylene is decomposed by the discharge.

Phosphorescence produced by the Discharge.

The discharge without electrodes produces a very vivid phosphorescence in the glass of the vessel in which the discharge takes place; the phosphorescence is green when the bulb is made of German glass, blue when it is made of lead glass. Not only does the bulb itself phosphoresce, but a piece of ordinary glass tubing held outside the bulb and about a foot from it phosphoresces brightly: while uranium glass will phosphoresce at a distance of several feet from the discharge. Similar effects, but to a smaller extent, are produced by the ordinary spark between the poles of an electrical machine.

The vessel in which the discharge takes place may be regarded as the secondary of an induction coil, and the discharge in it shows similar properties to those exhibited by currents in a metallic secondary. Thus no discharge is produced unless there is a free way all round the tube; the discharge is stopped if the tube is fused up at any point. In order that the discharge may take place, it is necessary that the molecules of the gas shall be able to form a closed chain without the interposition of any non-conducting substance; indeed, the discharge seems to be hindered by the presence in such a chain of any second body, even though it may be a good conductor of electricity. Thus, when a tube such as that in Fig. 7 is used, which has a barometer tube attached to it, so that by raising or lowering the vessel into which the tube dips a mercury pellet may be introduced into the discharge circuit, the spark-length

Digitized by Google

in the primary circuit may be so adjusted that a discharge passes when there is a clear way round the tube, but stops when a pellet of mercury is forced up so as to close the gangway. I noticed a similar effect in my experiments with a long vacuum tube described in the *Proceedings* of the Royal Society for January, 1891.

I had another discharge tube prepared, of which a section is shown in Fig. 8, *a*, in which a diaphragm (A B) of thin copper plate was placed across the tube; the diaphragm happened to catch at the bottom of the tube, so that it divided the latter rather unequally, and left a narrow passage round its edge. As much of the discharge as there was room for went round the edge of the plate; the remainder was not able to get through the copper, but formed a closed circuit by itself in the larger segment of the tube. In another tube, which is represented in section in Fig. 8, β, the copper diaphragm was attached to the walls of the tube by sealing-wax, so that there was no free way: in this case the discharge again refused to go through the copper, and split up into two separate discharges, as in the figure. When the tube was divided by copper diaphragms into six segments, as in Fig. 8, γ, no discharge at all would pass through. When the primary was slipped up the tube above the diaphragm a brilliant discharge was obtained. These four experiments all illustrate the difficulty which the electricity has in getting transferred from a gas to another conductor.

Fig. 7.

There is no discharge through the secondary, if it is of such a kind that, considering a closed curve drawn in it, the electromotive intensity as we travel along the curve tends to polarise the particles in one half of the chain in one direction, and in the other half in the opposite direction, the direction being reckoned relative to the direction we are travelling round the curve. Thus, for example, if we take a tube whose axis is bent back on itself, as in the figure, the electromotive intensity will tend to polarise the particles in one part of the chain in the direction of the arrow, and those in the other in the opposite direction; it is impossible to get a discharge through a tube of this kind.

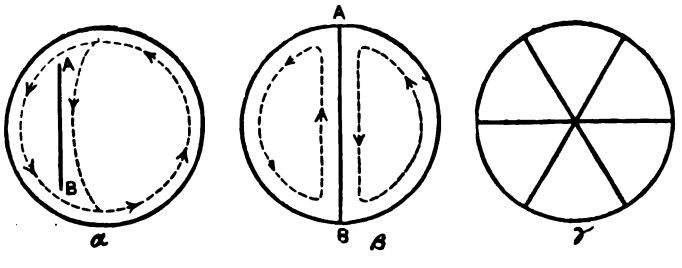

Fig. 8.

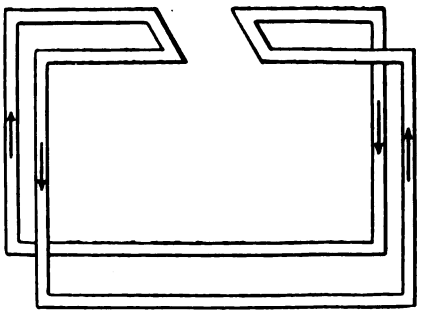

Fig. 9.

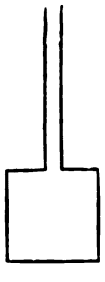

Fig. 10.

On the other hand, the molecules exhibit remarkable powers of making closed chains for themselves when not actually prevented by the action of the electromotive intensity. Thus the discharge will pass through a great length of tubing in the secondary, even if it is bent up as in Fig. 10, where the vertical piece in the upper part of the secondary is at right angles to the direction of the electric force, and where the molecules will receive no help in forming closed chains from the action of the external electromotive forces. I have succeeded in sending discharges through tubes of this kind 12ft. to 14ft. in length.

Screening Effects Due to the Currents in the Tubes.

One very noticeable feature of these discharges is the well-defined character of the ring, if the pressure is not too low. If a large bulb is used for the secondary with the primary just outside it, when the sparks pass between the jars a bright well-defined ring passes through the bulb near to the surface of the glass, the gas inside this ring being, as far as can be judged, quite free from any discharge. If now a bulb whose diameter is less than that of the luminous ring is inserted in the primary in place of the larger bulb, a bright ring will start in this, though at this distance from the primary there was no discharge in the larger bulb. Thus, when the large bulb was in the primary, the discharge through its outer portions screened the interior from electromotive forces to an extent sufficient to stop a discharge which would otherwise take place.

The screening action of these discharges is also shown by the following experiment. A, B, C, Fig. 11, is the section of a glass vessel shaped like a Bunsen's calorimeter; in the inner portion A, B, C of this vessel an exhausted tube is placed, while a pipe from the outer vessel leads to a mercury pump and enables us to alter the pressure at will. The primary coil, L, M, is wound round the outer tube. When the air in the outer tube is at atmospheric pressure, the discharge caused by the action of the primary passes in the tube E inserted in A B C; but when the pressure in the outer tube is reduced until a discharge passes through it, the discharge in the inner one stops; the discharge in the outer tube has thus shielded the inner tube from the action of the primary. If the exhaustion of the outer tube is carried so far that the discharge through it ceases, that in the inner tube begins again. It requires very high exhaustion to do this, and as on account of the joints it is unsafe to make the vessel very hot during the pumping, I have found it impossible to keep a vacuum good enough to show this effect for more than from half to three-quarters of an hour; in that time sufficient gas seems to have escaped from the sides of the vessel to make the pressure too high to show this effect, and it then takes from two to three hours' pumping to get the tube back again into its former state. An interesting feature of this experiment is that for a small range of pressure, just greater than that at which the discharge first appears in the outer tube, there is no discharge in either of the tubes; thus the action of the primary is screened off from the inner tube, though there is no luminosity visible in the outer one; this shows that a discharge equivalent in its effects to a current can exist in the gas without sufficient luminosity to be visible even in a darkened room. We shall have occasion to mention other cases in which the existence of a discharge non-luminous throughout the whole of its course is rendered evident in a similar way.

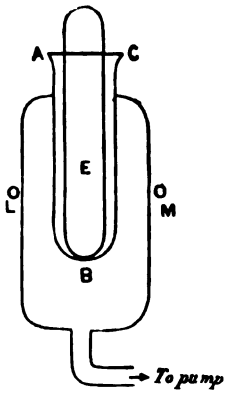

Fig. 11.

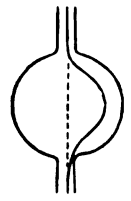

Fig. 12.

Another experiment by which the screening can be effectively shown is to place the primary coil inside a bell-jar which is connected with a mercury pump, the electrical connections with the primary being led through mercury joints. An exhausted bulb is placed inside the primary, the bulb being considerably smaller than the primary, so that there is an air-space between the two. Before the bell-jar is exhausted the discharge passes through the bulb, but when the bell-jar is exhausted sufficiently to allow of the discharge passing through the gas outside the bulb the discharge in the bulb ceases, and the only discharge is that outside. I have never been able to exhaust the bulb sufficiently well to get the discharge outside the bell-jar to cease, and that in the bulb to appear again, as in the preceding experiment. In this experiment, as in the preceding one, there was a range of pressure when neither the bulb nor the bell-jar was luminous, showing again the existence of currents in the gas which are not accompanied by any appreciable luminosity.

A curious bending in of the discharge which takes place in a square tube provided with a bulb can, I think, be explained by the principle of shielding. The discharge in the bulb does not, unless very long sparks are used, take as its course through the bulb the prolongation of the direction of the tube, but is bent in towards the primary. In Fig. 12 the dotted line represents the course the

discharge would have taken if there had been no bulb, the continuous line the course actually taken. This bending-in can be explained by supposing the currents started near the primary to shield off from the outlying space the action of the primary, and thus make the electromotive intensity along the axis of the tube smaller than it would have been if no discharge had been possible between the axis and the primary circuit.

(To be continued.)

ON SOME DETAILS IN THE CONSTRUCTION OF MODERN LANCASHIRE BOILERS.*

BY SAMUEL BOSWELL, OF MANCHESTER.

The great advance in engineering, due to the use of higher steam pressure, has brought about numerous improvements in the design and construction of Lancashire boilers, which however in many points are still far from perfect. The subject will be dealt with under the general headings of material, construction, and testing.

Steel.—At the present time the most suitable material that can be used for the construction of Lancashire boilers is believed to be mild steel manufactured by the Siemens-Martin open-hearth process, which is preferred to that made on the Bessemer process because it is generally found to be more homogeneous and reliable.

Test Strips.—When the plates have been delivered to the boiler works, strips are sometimes cut off for testing purposes. Those taken from the manhole scrap generally give the best results, because any surface imperfection or lamination is least likely to be found in the centre of the plate; consequently, such tests are most favourable to the steel maker. Strips cut from plate ends are far more likely to expose defects, such as blisters, overlapping, deficient thickness, uneven surfaces, and hardening due to the chilling effect of throwing plates hot from the rolls down upon the cold plate-floor.

When plates are ordered for the best boilers, it is generally agreed that their tensile strength shall be not less than 26 tons per square inch and not more than 30 tons, while the elongation must not be less than 20 per cent. in a length of 10in., the test strips being usually 2in. wide. In the bending test, the strip should be bent cold to a radius $1\frac{1}{2}$ times its thickness, until its ends are parallel with each other; and in the chill or temper test to a radius equal to twice its thickness. With plates from the best works there is no difficulty in getting these results.

Sizes of Plates.—As regards width, 3ft. to 3ft. 6in. is found most reliable, and most convenient on account of the spacing of the mountings on the boiler crown. As to length, one plate to a ring is undoubtedly the best arrangement, because it allows all the longitudinal seams to be near the crown, and they are then always accessible, above water level, out of the way of corrosion, and clear of brickwork. But where there is not machinery suitable for handling such long plates, then two plates to a ring must be adopted, care being taken to keep the longitudinal seams clear of the seatings.

Form of Seam.—The butt joint with double butt-straps is without doubt the best and strongest, the plates can be bent to a true circle, and the rivets are in double shear. In bending the plates for lap joints, there is only a slight deviation from the true circle; but in thick plates this occasionally leads to some slight damage in closing the joints at the corners where they have been thinned.

Thinning of Corners.—In most of the best boiler-works the corners of the plates are thinned by planing them down; but this in the writer's opinion is not the correct thing to do, unless the plates are made to a special shape. No doubt it obviates local heating and consequent internal strains in the plate. The writer has tried several experiments to ascertain the effect of heating plates locally. In one case a piece of steel boiler-plate was bulged out of shape in the middle, made hot at the bulge, hammered back to its original form, and planed into seven strips, which were then tested, showing that the local heating did not appear to have influenced the strength or ductility of the plate in the slightest degree.

With butt joints the thin corners of plates are got rid of; and sometimes the same principle is carried even further, as shown by making the butt-strap ends to butt against the edge of the next plate. This certainly makes a neat finish, but it is not so reliable as when the strap ends are thinned and tucked under the edge of the next plate.

Edges of Plates.—These are invariably planed in all the best works. The edge should be planed to the angle most suitable for calking. When planed to the angle of 75deg., then after fullering, which really means calking with a tool equal in thickness to the plate, the angle or bevel of the plate should be 80deg.

Bending of Plates.—Care should be taken to see that the sweep of the plate is carried to the very extremity in the bending rolls, so as not to require the ends setting to the curve with hammers. The plate is often hurried through the rolls, and is even bent to the full sweep at one operation, which should never be allowed.

Drilling.—In order to hold the plates in position without a number of tack holes, inside and outside angle-rings are sometimes employed, with a number of set-screws in each, by which the plates are held in a circular form; but whether they are really drawn up metal to metal as tight as they should be is to the writer doubtful. His own idea of really good tight work is to drill first a number of small tack holes, say $\frac{5}{8}$in. diameter and about 3ft. apart along the longitudinal and the circular joints alike, and to drill the joint holes with $\frac{1}{8}$in. draw, so that when bolting up in readiness for the drilling machine a drift can be inserted and the plates drawn up and bolted metal to metal, thus insuring good work; the $\frac{5}{8}$in. holes can easily be drilled out finally to the proper size after the bolts have been taken out. No doubt the use of the drift may be objected to; but in the writer's opinion it is in many cases essentially necessary to use it if good work is required. In most boiler-works it is denied that any use is made of the drift; but where is there a works without it? and although no tool is more misused, yet, when properly used as above described, what tool will do so much good work? It is only in the hands of inferior workmen, and with inferior material, that the drift is said to be worse than useless; but it only exposes that which should not exist, and in this connection, therefore, it has an unmerited bad name.

After drilling, the plates should be taken asunder, and the holes cleared of the burr left by the drills. With a proper tool this is not a difficult task, but it is important that it should be done, and, in the writer's opinion, the holes should even be slightly countersunk round the outer edge in order further to strengthen the riveting, especially where the rivets are in tension. It is when the plates are taken asunder that it can be discovered whether or not they have been drawn tightly together, metal to metal. If they have been put together as already suggested no burr whatever will be seen between the plates, and no trace of slackness will be visible when they are again put together for riveting up.

Riveting.—The proper diameter of the rivets will be influenced by the thickness of plate through which they pass. In the pitch, not only strength but steam tightness must be considered; occasionally, therefore, the adoption of the strongest pitch is precluded on account of steam tightness, though the writer believes that wider and stronger pitches than at present used may be adopted without fear of leakage, particularly when steel rivets are employed, put in properly heated, and well closed into the holes. When rivets are thrown into the rivet furnace by the bagful, and then brought out by the shovelful, often thickly coated with oxide and slag, it is next to impossible to make good work. There seems no reason why the rivets should not be heated to a bright red heat, brought out singly, and each rivet passed through a fine spray of water, which would immediately chill any oxide or slag and cause it to shell off, without in any way affecting the rivet itself; and then a perfectly clean rivet would be put in a perfectly clean hole.

Too much care cannot be exercised in seeing that the riveting is well done, both at the machine and by hand. If the rivets are not well closed in the hole, the previous attention to their size and cleanliness will be so much time wasted. To close a rivet well in its hole, it must be neither too hot, nor too slack in the hole, or else it will bend before it will thicken; and then it is impossible to fill the hole, however powerful the machine may be. The compression which acts on the rivet should not come upon it too suddenly, nor be of too short duration; but should rather be slow, so as not to leave the closed rivet at too high a temperature. Perhaps the best means of judging good sound riveting is to stand by when it is being done, and to notice how long the rivet remains hot. When a clean rivet is well closed in tight, it will go black immediately, showing that the colder metal round the hole has come in direct contact with the rivet and has abstracted the heat from it; while a slack or dirty rivet badly closed will remain hot for a considerable time. This will be seen at once by watching a good riveting machine, and then watching a set of hand riveters, who seem to be giving more attention to the appearance of the rivet than to its usefulness and purpose. When engaged in piece-work on girders, it is astonishing how expeditiously the men can get through riveting, particularly when snap riveting. A few light blows from the hammer-panes are sufficient to form a rough head, and then half a dozen blows on the snap finish the rivet while it is still at a bright red heat; but the body of the rivet has never thickened in the hole, simply because the light blows have not had any effect except just at the point where the snap head is formed. What is wanted is that the rivet should be well forced into the hole, either by a steady pressure from a machine, or by a succession of good blows fair on the end of the rivet; and the size or shape of head thus formed are only a secondary consideration.

* Abstract of a Paper read before the Institution of Mechanical Engineers.

Welding Flues.—For welding, long fires are used, with a pair of long parallel tuyeres, each containing a row of small blast-pipes, so that a full heat may be obtained along the whole length of the seam at once if required. When the rings of plates are welded under the steam hammer, three heats are often found sufficient to finish a ring of plate 3ft. 6in. wide. After welding, every ring should be carefully heated to a dull red along the weld, and be allowed to cool slowly, so as to anneal the portions that have been hammered, and thus set free any internal strains set up in the welding.

Circular Joints.—For the circular joints connecting the several rings of plates forming the flue, the ordinary lap-jointed seam is far too weak for the high pressures now in use, and may therefore at once be discarded. The seam most generally adopted is the Adamson flanged joint, but few even of the best makers seem to bestow as much care on it as was done by the originator himself. The radius of the flanging is generally less than desirable ; and the liner ring of soft iron is not always of the proper shape. Among the strengthening seams that are in use, there is one known as the Bowling or Bolton hoop, which perhaps for most purposes is a better seam than the Adamson flanged joint. The hoop should be put on hot, but should not be shrunk on the flue rings too tight, only tight enough to bring the hoop and rings together, metal to metal. If put on too tight, there is not only a difficulty in removing the hoop after drilling, but there is a probability that in the flue rings grooving or channelling will set in round the edges of the hoop, after the boiler has been at work a short time. Like the shell, the rings forming the flues should be put together blank, or with a few tack or guide holes, and then drilled in position, all burrs being removed before the insertion of the rivets ; and the same care should be exercised as in shell riveting.

Calking.—The next process is calking, which deserves more attention than is occasionally bestowed upon it. In some shops a number of youths are employed, into whose hands the calking tools are put without any instructions as to their proper use. When this mistake is made they are sure to do more harm than good, increasing the tendency to leakage, and rendering it almost impossible for another man to make the work good afterwards ; and they may niche the plate in such a manner as to lead to a serious fracture. All the tools used for calking should be ground to one uniform bevel, excepting only for special or corner work. When the plate edges are planed to the proper angle, it is easy for a practised eye to detect any irregular work. Calking never strengthens a seam, but often weakens or damages it ; and before long the writer believes that seams will be made tight without calking by hand tools, and that this will be accomplished either mechanically by abrasion, such as that produced by the friction of the edge of a revolving disc pressed hard against the edge of the plate, or else by the use of paint or cement.

End Plates.—The shell and flues having been calked are ready for being put together, and for the ends to be marked off. In building up a shell or flue, say 30ft. long, however carefully done there is always a tendency to creep, so as to be $\frac{1}{16}$in. or $\frac{1}{8}$in. longer or shorter than intended. This difference must, therefore, be made up in such a manner that the end plates shall be quite flat, without the slightest straining; for any strain existing in the boiler while at rest would certainly be increased when at work. Fortunately the best methods of connecting the end plates to the shell and flues are such as will accommodate any little difference there may be in length between shell and flues, the front end being secured to an outside angle-ring, while the back end is flanged and fitted inside the shell. The flues having been run in, the front end plate is bolted up first, the back ends being left quite free. The back end plate is next put in place, and its flange is forced into the shell until the plate itself is close up to the flue ends ; the holes in the flange are then marked with a centre punch, and the end so centred is taken down and drilled ; after which all will go together, and can be bolted up and riveted without producing the slightest pull on any part, every portion being left in a state of rest.

As the end plates are flat, they require more care than any other part, in order to ensure that they shall be of the proper thickness and efficiently stayed without rendering them too rigid. As it is, however, if the end plates of a boiler are not properly designed, their strength rapidly becomes weakness. They must be sufficiently pliant to yield to the varying expansion and contraction, without failing under steam pressure; and practice has shown that, in well-constructed Lancashire boilers, end plates $\frac{1}{2}$in. to $\frac{7}{8}$in. thick, when properly secured to the shell and flues and properly stayed, may be used with safety for pressures up to 100lb. per square inch.

Gusset Stays.—In regard to the position and mode of attachment of gussets, it will readily be admitted that the most uniform distribution of the load will be the best. The attachments to the shell will therefore be on the first and second rings of the shell alternately, with gusset plates between double angles, so that the rivets will be subject to a double shearing strain ; and the angles sh uld be arranged sufficiently close together to have a fair grip on the gusset plate. As boilers of different diameters have the gussets radiating from different points, the angle of attachment will vary accordingly ; and therefore the general custom is to knock the angle to a suitable bevel : a piece of work which is rarely satisfactory, but as it is in a position somewhat inaccessible it is often allowed to pass, while if it were more visible it would certainly be condemned. It is of course advisable to have all gusset angles made of mild steel, so as not to be troubled with the reedy fractures so often found in angle iron and iron bars of similar section.

Longitudinal Bolt Stays. When the end plates are well supported by gussets, longitudinal bolt stays are considered by the writer to be unnecessary. When the required support can be given to each end plate independently of the other, as it is by gussets, it is not advisable to tie the two end plates together by rigid tension bars, such as the longitudinal stays often are. If the shell were weak in a longitudinal direction, then the support afforded by longitudinal bolt stays would be useful ; but seeing that there is already an excess of strength in the shell longitudinally, the rigid bolts are worse than useless, inasmuch as they interfere not only with the accessibility of the interior, but also with the application of such fittings as the low-water safety-valve, and, what is most important, with the expansion and contraction of the flues and shell. Whenever these bolt stays are applied as a secondary support, they should be left slack enough to allow of the boiler attaining its maximum length by expansion before they are tight ; and a good rule of thumb is to allow them to sag downwards, say 4in., when cold. A loose hanger should be added to carry the weight of the stays, so that in case of transit the vibration shall not be likely to break them, as has many times been the case. Where there are no gussets, then longitudinal stays serve quite another purpose ; and in many cases where they have been used in cylindrical boilers externally fired they have served a good purpose, when seam rents have occurred, in keeping the parts together ; and, although they have not prevented an explosion, they have reduced the extent of damage to narrower limits.

Mounting Blocks or Stand-pipes.—These are now generally made of wrought-iron or mild steel, and by two different processes. In some cases they are made of angles of special section ; in others they are made of ordinary plate cut to shape, flanged at both ends, and the top flange strengthened by having a plate or washer welded to it. The latter process appears preferable to the use of angles, because with angles it is not an easy matter to bring to shape a heavy section of material, such as is required, without the risk of making an unsound weld. For size of opening it is found that 1ft. 4$\frac{1}{2}$in. diameter is sufficiently large to admit any ordinary man to pass through, or any of the internal fittings used in the boiler. The manhole cover should also be of wrought-iron or mild steel, of not too heavy a section, say 1in. thick, cambered 2in., and secured by sixteen bolts of 1in. diameter. Such a manhole and cover have been tested by water pressure to 1,000lb. per square inch, without the slightest sign of distress. A light cover is more easily handled and jointed than a heavier one ; and with a good number of bolts, the failure of any bolt, or the oversight of one not being screwed up tight is of less importance than if only a dozen bolts were used of 1$\frac{1}{2}$in. diameter, as is often the case at present.

Hydraulic Testing.—The final stage through which the boiler has to pass before leaving the maker's works is perhaps the most important, though not always so regarded. It has often been argued that the hydraulic test is of little use ; in this view, however, the writer does not entirely agree, for although the Lancashire boiler is of such a form that the strength of every part may be ascertained with a fair amount of accuracy, still the hydraulic test has before now revealed defects which would otherwise have escaped notice. For instance, the gussets may to outward appearance be good and firm, and yet may be fractured through the line of rivets ; and the same might be the case with the bottom flange of the manhole. Many parts may be overlooked by the workman ; and even the foreman cannot be expected to see every little detail. For testing a boiler the writer's recommendation is to proceed as follows : after making all joints good, connect a small steam-pipe, and turn steam into the boiler until there is a pressure of 3lb. or 4lb. per square inch, when any leakages at places not soundly calked or at loose rivets can readily be found. These can then be chalked, and the steam blown out ; the boiler being warm will soon get dry for the men to calk the leaky parts, which when dry are made good with about half the trouble entailed in calking a wet seam ; in fact, it is often impossible to calk a joint tight with a layer of water between the plates. After calking the visible leakages, every fitting intended to be used when in working trim should be placed in position, the boiler filled with cold water, and tested by slowly increasing the pressure until the working pressure is reached, when a general survey should be made of all parts of the shell and the inside of the flues ; any leakages should be marked, the pressure released, and all weeps calked. Then should follow the final test, which

Digitized by Google

may be arranged either with the fittings in position or with blank flanges on the stand-pipes; and the required pressure should be provided for by properly loading the safety-valves.

Here it has to be decided what is the proper test-pressure to apply. Testing the boiler to ascertain its fullest strength would mean testing it to destruction; and even before this extreme was reached the boiler would be seriously injured. There is, therefore, what seems a great difference of opinion among engineers as to the proper limit of test pressure, which has been variously given at from 1½ times to twice the working pressure; but a closer consideration goes to show that there is not a great difference after all. For those who go in for a high test-pressure go in also for a high factor of safety; and those who advise a moderate test-pressure require only a moderate factor. For instance, a test of double the working pressure with a factor of 6 is about equivalent to a test of 1½ times the working pressure with a factor of 4½; in each case the test-pressure amounts to one-third of the assumed bursting or collapsing pressure, and is a test that may safely be applied to most materials in engineering. The safest plan, therefore, appears to be to arrive at the bursting and collapsing pressures by careful calculation, and then to adopt a test-pressure accordingly.

For the final test the boiler should be again filled with water, and all parts carefully gauged when at rest. The flues should be gauged both horizontally and vertically; and a good way of doing this is to fix light battens across, the lighter the better, just tight enough to hold themselves in position at right angles to each other; when under test, any deviation from the original form will at once show itself by bending one batten and allowing the other to fall out; the amount of deflection can then be easily measured. The flat irregular surfaces of the end plates, however, are the most important, and should be carefully lined off, and light strings stretched tight across at say one inch distance from the plate; then, by inserting a paper gauge or wedge between the string and the end plate, the slightest trace of yielding can be discovered, measured, and recorded. After seeing that all is in readiness, the pressure may be applied up to the working limit, at which all parts should be carefully gauged and noted. Should there be no yielding of importance, then the pressure may be increased up to the test limit by gradual increments of 10 lbs. or 15 lbs, a sharp watch being kept on all sides at each increment. When the ultimate limit is reached, a strict examination should be made of all parts, and accurate gaugings taken; these will generally occupy about half-an-hour, during which time the pump should not be used, in order that any fall of pressure may then be seen. If the pressure has been maintained within one or two pounds during this time, it may then be released, and gaugings again taken, and compared with the original gaugings taken before the pressure was applied, when any permanent set or deflection will be at once apparent. If so far satisfactory, the water may be run out; and a careful examination of all internal parts should be made, particularly of the gussets, and of all rivets that are in tension, as these do occasionally go wrong, especially in inferior work or with indifferent material.

If all parts have been found to stand the testing satisfactorily, the boiler may be pronounced quite equal to the requirements. If when forwarded to its destination it should happen to have been subjected to unusually rough treatment during transit, it is a good plan to have it placed over its seating ready for building in, and then to fill it with cold water, when any of the seams that may have been shaken can be re-calked; but there is no necessity for any further test.

HIGH AND LOW POWER INCANDESCENT LAMPS.*

In *The Electrician* of September 25 there is a comparison between the ordinary incandescent lamp of 10 or 16 candles and lamps of 500 or 1,000 candles. This comparison sets forth the great advantage of using the latter. The question being a very interesting one in practice, we propose, without wishing in the slightest degree to call the author of the article to account, to examine the figures he quotes. We give his figures in the following table:—

Cost of 500 Candles for 1,000 Hours.

Type of lamp employed.	Energy expended at ·0725fr. for 100 watts.	Price of lamps.	Total expenditure in francs.
32 16-c.p. lamps, taking 4 watts per candle, and costing 4·7fr. each	1,470	150·4	1,620·49
1 500-c.p. lamp, taking 2 watts per candle, and costing 28fr.	735	28	762
		Difference,	858·49

* From *La Lumière Électrique*, October 31, 1891.

Presented in this manner, the comparison between the two types of lamp, the 16-candle lamp on the one hand and the 500-candle lamp on the other, relates to two points—the cost of the lamps, and the energy expended per unit of light. The price of the 16-c.p. lamp is set down at 4fr. 70 centimes. This very high figure is perhaps correct for England, but in any case it is only temporary, and in all other European countries the price is now under 2fr. The energy expended in the lamp is put down at 4 watts per candle for the 16-candle lamps, and at 2 watts for those of 500 candles. Here also we think there must be a gross error.*

One can make 2 watt 500-candle lamps as one can 2 watt 16-candle lamps; but either the life of these lamps will be at the most 50 to 80 hours, or at the end of a short time the amount of light they emit will have greatly diminished. Tests which we have carried out on lamps of 500 and 1,000 c.p., relate to a small number of lamps; but we have ascertained that when worked at 2 watts their illuminating power decreases by at least 30 per cent. after a 20 hours' run. After this fall the lamp runs at 3 or 4 watts per candle, and lasts, like its congeners of the same type, 800 or 1,000 hours. In fact, from the point of view of cost the only difference lies in the purchase price, which will be for an illumination of 500 candles for 1,000 hours—

(i.) Using 32 16-c.p. lamps, at 2fr. each	64fr.
(ii.) Using one 500-c.p. lamp, costing 28fr.	28fr.
Difference	36fr.

It now remains to attack the question from another point of view, which is, the useful effect produced by the two types of lamp. Now it is incontestable that everywhere where the glow lamp is preferred to the arc lamp there is good reason to multiply the sources of light, as much for the artistic effect as for the proper utilisation of the light. For instance, it is certain that for the lighting of an office the illumination given by 32 16-c.p. lamps might be satisfactory, while that produced by a 500-c.p. lamp would be defective.

To resume, while we think that one of these types may be preferable to the other in special cases, yet, generally speaking, from the point of view of economy, having regard to the light utilised, the advantage rests with the lamps of low illuminating power.

LEGAL INTELLIGENCE.

The Cadogan Electric Light Company.

On Saturday last there were two petitions before Mr. Justice Kekewich for winding up the Cadogan Electric Light Company. The first was presented by Mr. H. Lowenfeld, who asked for a winding-up order under the supervision of the Court; and the other was presented by Mr. E. E. Johnson, who asked for a compulsory winding-up order.

Mr. WARMINGTON, Q.C., in supporting the first petition, said his case was that, notwithstanding the voluntary liquidation which was commenced in February, the Company had been going on the same as before; and having read the liquidator's affidavit, his statement was—and the liquidator did not appear to contest it—that since the liquidation some creditors had been paid and not others, and he asked for an order because, he said, the liquidator had no right to prefer one creditor to another, but should pay all creditors equally. The learned counsel referred at considerable length to affidavits which had been filed by the liquidator and others, with a view of showing that it was necessary that an order should be made with a view to protecting the interests of creditors and others.

Mr. V. SMITH supported the second petition, asking for a compulsory winding up, contending that this was not a case which could be properly met by a supervision order.

Mr. WAGGETT, on behalf of the liquidator, said that with regard to the supervision order which was asked for, he could not, on behalf of the voluntary liquidator, say that he would object to be supervised if his Lordship thought that it was necessary; but he contended that no case whatever had been made out for a supervision order. He opposed most strenuously the making of a compulsory order, and affirmed that the petition asking for such an order had been wrongly presented.

Mr. JUSTICE KEKEWICH said that the case was not one in which there was any suggestion of fraud or matter of that kind requiring that the case should be placed in the hands of the Official Receiver. All that was needed was the protection of creditors. It was intended to hand over this Company's assets and business to a new company already formed, and in the carrying out of a transaction of that kind difficulties occurred in a

* It may be as well to state at once that the prices given were the current retail ones as per manufacturers' lists, and the same is true as regards the figures relating to watts per candle. Assuming equal veracity on either side, the object of the note criticised was to ascertain what life the more efficient higher candle-power lamp must have, taking into consideration the current price per B. T. U. supplied, in order not to cost more than its small competitor, which has an average life of 1,000 hours. The conclusions arrived at were somewhat surprising, and in many instances would undoubtedly have a practical bearing.—ED. *E.*

Digitized by Google

compulsory winding up which were not encountered in a voluntary liquidation. On the other hand, the case appeared to be one in which the rights of creditors might be prejudiced by a voluntary winding up if the liquidator spent the assets in carrying on the business and making fresh installations which would have to be paid for in ready money. His Lordship therefore made the usual supervision order on the first petition, and made no order on the second petition.

Latimer Clark, Muirhead and Co., v. Francis.

In the Queen's Bench Division of the High Court of Justice on Friday last week the case of Latimer Clark, Muirhead and Co. (Limited), v. Francis, came before Mr. Justice Grantham, sitting without a jury. This was an action brought by the plaintiffs, electrical engineers, against Colonel George Francis, in reference to the sub division of founders' shares in the St. James's and Pall Mall Electric Lighting Company.

Mr. Lawson Walton, Q.C., and Mr. Gurdon appeared for the plaintiffs, while Mr. Whitehouse represented the defendant.

Mr. GURDON, in opening the case for the plaintiffs, said his clients and the defendant were joint founders of the St. James's and Pall Mall Electric Lighting Company, which was incorporated on the 2nd of March, 1888, and which was doing exceedingly well. By an agreement dated April, 1888, and scheduled in the Articles of Association between the Company and the founders, it was provided that the capital should be £100.000, divided into £19.980 ordinary shares of £5 each, and 100 founders' shares of £1 each. The founders guaranteed that 5.000 ordinary shares should be taken up by responsible persons by the 13th of April, 1888. For that the founders were to have allotted to them or their nominees 100 founders' shares in the Company, and the founders agreed to make over 25 founders' shares, or one share to every person who applied for 200 ordinary shares out of the first 5,000 allotted. The 5,000 shares were taken up or placed in due time, and the parties became entitled to the founders' shares. On the morning of July 13th the defendant appeared at the plaintiffs' offices, and produced a list of the persons to whom he proposed to have the shares allotted, which was objected to.

His LORDSHIP said he understood that the shares were to be allotted as the founders respectively desired.

Mr. GURDON remarked that they were to be allotted as the plaintiffs and defendant desired. By the defendant's list more than 20 went to his nominees. The plaintiffs refused to sign it. The defendant said it must be signed that day for Somerset House, and that if the plaintiffs signed it he would afterwards adjust the shares and put them right. That was the basis of the claim.

His LORDSHIP: You say the defendant refused to rectify it?

Mr. GURDON: Yes.

Mr. WHITEHOUSE said the defendant's case that the shares were allotted by the Company with the full knowledge of the plaintiffs, and that everybody on the list was entitled to founders' shares, and it was assented to by the plaintiffs at the time.

His LORDSHIP inquired whether the learned counsel's contention was that the list represented the agreement between the parties, and was signed by the plaintiffs without any reservation of any kind.

Mr. WHITEHOUSE applied in the affirmative.

Mr. GURDON, resuming, explained that there was a counter claim with respect to the disposition of the 25 founders' shares in question and some preliminary expenses.

Mr. WHITEHOUSE said the St. James's Company was now practically under the domination of Mr. Latimer Clark and his friends. Colonel Francis, who was a Director, had been voted out by the plaintiffs' contingent.

Mr. GURDON said he denied the accuracy of that statement.

Mr. WHITEHOUSE said the list was signed and agreed at the time. Colonel Francis afterwards called on Mr. Latimer Clark because he had told him that his partner was dissatisfied. Then Colonel Francis said if anyone else should turn up who was entitled to a founders' share they would have to give him one. No one else had turned up, and the defendant was, therefore, under no liability.

His LORDSHIP said there was a letter which indicated that a readjustment was contemplated. It might be that the defendant did not mean anything of the kind.

The plaintiffs then called evidence with the object of showing that a readjustment of the founders' shares was necessary.

At the conclusion of the evidence his LORDSHIP held that no cause of action had been proved, and entered judgment for the defendant, with costs.

Mr. WHITEHOUSE said he would withdraw the counterclaim without prejudice to any further proceedings that might be necessary hereafter.

Uniacke v. Scott—Scott v. Uniacke.

On Thursday last week the above actions came before Mr. Justice Romer in the Chancery Division of the High Court of Justice.

Mrs. Mary Augusta Uniacke, the plaintiff, was a widow, and on the 19th of December, 1889, she, her son, F. W. P. Uniacke, and the defendant, Mr. Ronald Augustus Scott, of Acton-hill, an electrical engineer, executed in duplicate a deed by which F. W. P. Uniacke was apprenticed to the defendant for three years, from the 25th of December, 1889, agreeing to serve and not unlawfully absent himself, &c. By the same deed the defendant, in consideration of a premium of £150, agreed to receive Uniacke as an outdoor apprentice in the art of an electrical engineer, providing the apprentice should "serve his master faithfully and well, and in accordance with the rules and regulations of this establishment," and to pay him 7s. 6d. per week during the first year, 10s. per week during the second year, and 15s. per week during the third year. The plaintiff alleged that the defendant had committed various breaches of the agreements on his part contained in the deed, and in particular, *inter alia* (1) that he had not at any time properly taught or instructed F. W. P. Uniacke, or caused him to be properly taught or instructed, in the art or business of an electrical engineer: (2) that the defendant in September, 1890, without due cause, suspended F. W. P. Uniacke from attending, and refused to allow him to attend at the workshops and places of business of the defendant for one month: (3) that the defendant had discharged F. W. P. Uniacke. The plaintiff accordingly claimed a return of the premium, or, in the alternative, damages. The defendant denied that he had discharged the plaintiff or been faithfully served by him: and alleged that the suspension was in accordance with the rules and regulations exhibited in conspicuous parts on the works; that the apprentice had repeatedly and without leave absented himself from the workshops, and when there he had been very negligent. The defendant also alleged that the plaintiff had admitted that her son's heart was not in the work, and that both he and his mother were anxious that he should be discharged from his apprenticeship, and, without alleging any breach on the defendant's part, had requested the defendant to cancel the indenture. The defendant also denied any breaches on his part of his agreement to instruct, and counterclaimed, in respect of alleged breaches by the apprentice, for the sum of £50 as damages. The effect of the evidence is sufficiently stated in the judgment of his Lordship. The letter of October 27th referred to in the judgment was as follows:—

"Dear Sir: As you have known for some time now that I do not care for electrical engineering, I am writing to you to beg you to cancel my indentures. I have no fault to find with the works, but it was a mistake on my part ever to have tried electrical engineering. I trust that under the circumstances you will consent to return a reasonable portion of my premium.—I remain truly yours, FRANCIS UNIACKE."

Mr. Neville, Q.C., and Mr. J. W. Baines were for the plaintiff; and Mr. Haldane, Q.C., and Mr. H. Terrell were for the defendant.

Mr. JUSTICE ROMER, in giving judgment for the plaintiff, said the defendant's business was somewhat peculiar. He had very few, apparently only seven or eight, workmen, properly so called, and a great number of pupils and apprentices. There were about 65 apprentices now, and at the date of the apprenticeship deed there were about 40. But his Lordship was not concerned with the question whether the defendant had taken too many pupils. It might be that he, nevertheless, did his duty to this particular pupil, and, even if he had not too many pupils, he might, nevertheless, have neglected his duty to this one. But the great number of pupils probably accounted for the neglect shown here. As to the first breach of duty alleged, his Lordship had to consider whether the defendant did commit a breach by not teaching and instructing the plaintiff's son. His Lordship had heard the evidence, and was very unfavourably impressed by the evidence of the defendant and his witnesses. The plaintiff's son, whatever little failings he might have, appeared to be a truthful young man"; and his evidence, where there was a discrepancy, was to be preferred to that on the other side. His Lordship was convinced that the son was not taught, or attempted to be taught, to any substantial extent, the art of an electrical engineer. He was only employed in handy work, which saved the whole or part of a workman's wages. For nine months he had been kept at two sorts of work only, viz., filing and fitting brass rods, and attending to a machine for making brass screws. No real instruction in electrical engineering had been given at all. One of the defendant's witnesses said Mr. Uniacke had been put on a lathe, but the apprentice denied this, and probably the defendant's witness had been misled by the fact of there being so many pupils. His Lordship quite agreed that, in teaching the art of electrical engineering, it might be very useful that a pupil should know something of the elements of the machinery and the articles used in the business; but that might be carried too far. There must be a limit to keeping the pupil to the elements of the business. The defendant was not justified in keeping the plaintiff's son for nine months at the mechanical work referred to. The son appeared to have been taught nothing. The defendant appeared to have left the business to his manager, and the manager to the foreman, and the foreman seemed to have looked on the pupil only as a person employed to do mechanical work. His Lordship held on the facts that the defendant had wholly neglected his duty, and was not surprised that the apprentice had disliked the work and been inattentive. He had been somewhat inattentive—principally by his absences, some of which had been caused by illness. But the inattention on his part had been grossly exaggerated. The defendant could not complain of this, having regard to his own neglect. No conduct of the plaintiff's son justified the defendant in his breaches of the apprenticeship deed. It was suggested by the defendant's witnesses that the plaintiff's son could not be taught this business, but, without attributing to him extraordinary ability, his Lordship was satisfied of his general intelligence. Under these circumstances the plaintiff's son became dissatisfied, and it was not surprising that his mother thought he had no heart for the business, and tried to get the deed cancelled, and obtain a return of part of the premium. After she had gone to India, the son's salary was reduced by the foreman, for some inattention, by 25 per cent. That was an ample punishment; but, on the son, complaining to the defendant, and merely because of such complaint, the defendant, not contenting himself with confirming what the foreman had done, suspended the son for a whole month, such suspension meaning that the son was not allowed to come to the works or receive any salary or instruction. That decision was unjustifiable. The defendant sought to justify it by referring to his rules and regulations; they were not brought to the attention of the plaintiff's son, if they were in existence at the date of the deed, or for some months afterwards. But the deed meant the rules and regulations for the time being, and the defendant might make reasonable rules and regulations. Nevertheless, a rule that for neglect an apprentice might be suspended for three months was unreasonable. At any rate suspension for a month in this case was un-

Digitized by Google

reasonable, and could not be relied on by the defendant. Under the circumstances the defendant had done what amounted to grave breaches entitling the plaintiff to sue for damages, on the double ground of the entire neglect of the defendant in doing his duty to the plaintiff's son, and his breach of duty by refusing to instruct him. The breaches were so grave that it would be unreasonable to suppose that the plaintiff was bound to send her son back for the remainder of the term, and it would be absurd to say that she was still bound to treat the deed as not having been broken and practically put an end to by the defendant. His Lordship was also dissatisfied with the defendant's conduct in another matter. There was a complaint on the 24th of October of his neglect to teach the art of electrical engineering. The defendant, finding he was complained of for neglect of duty, suggested to the plaintiff's son that he should write the defendant a letter saying that he had no complaint to make of the defendant's works, and represented to him, or induced him to believe, that on such a letter being written a portion of the premium would be returned. The plaintiff's son accordingly wrote the letter of October 27th, and the defendant had admitted that when he suggested this letter he had no intention to return any part of the premium. His Lordship considered this a mere trick to get an acknowledgment that the apprentice had no fault to find with the works and so defeat any claim for neglect of duty on the defendant's part. His Lordship was surprised that the son wrote the letter, or that such letter was not stopped by the solicitor who was consulted by him; but that letter would not avail the defendant in this Court, which could still look at the true facts. His Lordship was satisfied that there had been a total neglect of the defendant's duty. When the plaintiff returned from India she found that her son was no longer at the works of the defendant, who had acceded to her son's request that until his mother returned he should not be obliged to attend the works at all. The mother was justified in bringing the action, and was not obliged further to treat the deed as compelling her to send her son to work. The plaintiff was entitled, not to a return of premium, but to damages, which his Lordship assessed at £120. The defendant must also pay the costs of the action, and his counter claim would be dismissed with costs.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *October* 31, 1891.

Pittsburg Convention of the American Street Railway Association.—The Convention of the American Street Railway Association was a very notable gathering. In point of interest and enthusiasm it compared favourably with the Montreal Convention of the National Electric Light Association. Of the two the Street Railway Association is the more numerous and compact, and not only draws around it a large number of adherents, but tempts electrical manufacturers into making displays of no ordinary character. At Pittsburg, however, there was unfortunately no easily available hall suited for an electrical exhibition, and consequently the displays of the various companies were scattered around in a way that made it exceedingly difficult to form a good general idea as to what was really in place. A large barge moored in the river close to the Mornongahela House—the headquarters of the Convention—offered a habitation to a number of fine exhibits; but aside from this they were scattered promiscuously in the corridors and parlours of the hotel, and elsewhere in the vicinity. It is unnecessary to state that the Convention was of a very characteristically electrical character; all but two of the Papers were exclusively electrical. Of unusual interest were the Papers of Mr. G. W. Mansfield and Mr. O. T. Crosby, of the Thomson-Houston Company. The former gentleman gave an address on the various methods of supply that have been proposed in electric railroading. He is, like most electricians, an ardent advocate of the trolley system, not so much from any attributes of ideal perfection as from its intensely practical and workable characteristics. The conduit was in his opinion impracticable, at least under the conditions of climate with which American electricians have to contend; and any and all systems of rail supply he believed to be equally objectionable, unless in very peculiar situations. Mr. Crosby's Paper was a protest against the lack of standards both of rating and size, and in the nomenclature in the electrical railway business. Motors, he said, were usually rated by their alleged E.H.P., but this was indeed a most uncertain quantity, for the reason that the temptation was constantly before the manufacturers of electrical apparatus to rate their machines as high as possible, at their maximum rather than at their best available output. As a remedy he advocated classifying motors by the three factors of horizontal effort, speed, and efficiency. For example, he would describe a motor that gave 500 pounds horizontal effort and 60 per cent. efficiency at 10 miles an hour as a $500 \times 10 \times 60$ motor. This is unquestionably an improvement over the usual method of rating, but would create a constant temptation to exaggerate motor efficiency, which is well known to be low, sixty per cent., as noted by Mr. Crosby above, not being far from the correct figure generally. Further, the speaker advocated making all parts of electrical car equipment of a standard gauge, so that any motor could be fitted to any truck, and any trolley pole to a standard base. As regards nomenclature, he called attention to the wide variations between the practice of different companies, and the frequency with which they called the same article by different names. His suggestions in this line are well worth being followed. There is a tendency to the formation of a local electrical vernacular in every large manufactory. For example, the Brush Company has to shoulder the responsibility of the introduction of that very expressive term "nigger" into the electrical vocabulary, meaning thereby a short circuit burning and blacking field coils or cores. In a similar way the Westinghouse Company must be charged with the introduction of that very objectionable phrase "leakage current" to designate the slight current that flows through the primary of the transformer when the secondary is open. The Westinghouse Company threw open its great Pittsburgh factory, and it was visited by scores of delegates. No electrical company in the United States does more elegant and finished mechanical work than the Westinghouse; and the beautiful workmanship of their dynamos, motors, and subsidiary apparatus, won the universal commendation of every one who went through the factory. One of their most interesting exhibits was a gigantic multipolar generator in process of construction, intended to develope 500 E.H.P.; another smaller machine of a similar kind was shown running with a load, and its operation was perfectly smooth, noiseless, and sparkless when the load varied from nothing to 400 amperes at a single jump. In their factory, too, were shown the three types of Westinghouse motor truck—double reduction, single reduction, and gearless—arranged with Prony brakes, to exhibit their relative performances. A Westinghouse car, fitted with gearless trucks and gaily decked with banners, was one of the features of the Convention. The Short Electric Railway Company also had a gearless car on the road, and so confident were they of its good performance that they placed an ammeter and voltmeter upon it, and invited all who cared to do so to ride upon the car and measure for themselves the amount of power required. The result was, on the whole, decidedly satisfactory; for while the motors did not show a high efficiency they performed admirably, running cold and sparkless, handling the heavily loaded car with perfect ease on grades as high as five per cent. A number of test runs were made with this car, but the result of them has not yet been made public, although appearances seem to indicate that the power required was but little greater than that needed for the double or single reduction motors, the ratio being about three to two. It is proper to mention, however, that the Short Company was compelled to run—owing to other vehicles in the street—at a speed considerably below that for which it was designed. The Westinghouse car was put at even a greater disadvantage in this respect, as it was intended for a normal speed of 150 revolutions per minute instead of 100, as in the case of the Short; to this must be ascribed the fact that the Westinghouse Company made no car tests, and, indeed, it is reported to have peremptorily refused to allow them to be made, a somewhat unwise proceeding, even if apparently justified by commercial reasons.

The Edison Company exhibited a new single reduction motor. This machine shows a marked improvement over the original form, the design having been decidedly improved in the last four months.

The Thomson-Houston Company, in addition to other exhibits, showed the new iron-clad single reduction motor, of which I wrote you some few weeks since. They are now making these machines in considerable numbers, and its success is very gratifying. This motor is about the only one of the new crop of single reduction machines that shows any

Digitized by Google

striking originality of design, and the variations introduced in it are probably of more fanciful than real advantage.

Nothing was seen at the Convention either of Mr. Edison, who was reported to have promised to be present, or of his new plans for electrical traction I have mentioned previously. To simmer down the whole matter, he proposes to use a voltage of about 20 with the rails properly bonded together as conductors, and is of necessity compelled to cut up the line into comparatively short unit lengths to be fed by motor generators. The requisite amperage demanded by this scheme is something appalling even to the imagination, and the scheme is generally condemned by experts as ingenious but impracticable. The impression seems to be prevalent that Mr. Edison in a frolicsome mood has been romancing for the benefit of an over-credulous reporter. As regards his high-speed proposition, no one seems to know whether he seriously intends working out that line of work or not, although the Edison Company is known to be contemplating the problem of a high speed road in the West. Whatever may come of it, Edison is assuredly somewhat behind the times in announcing it as anything in the least degree remarkable, in view of the experiments made by Mr. O. T. Crosby several years ago, and the plan proposed for an electric road between Budapest and Vienna. Perhaps here, too, the great inventor was amusing himself at the expense of the reporter.

Mr. A. E. Kennelly on Magnetic Reluctance.—At the last meeting of the American Institute of Electrical Engineers, on Tuesday evening last, Mr. A. E. Kennelly read a very interesting and suggestive paper on Magnetic Reluctance, transforming the curves of magnetisation given by various authors so as to show more distinctly the characteristics of this particular quantity. Like all Mr. Kennelly's work it was clear, thoughtful, and entertaining.

SCANDINAVIAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

COPENHAGEN, *November* 4, 1891.

The work in connection with the large central station at Copenhagen is now approaching completion, and although the plant will not come into operation as soon as it was originally intended, it will probably do so early next year. The position of the station is as central as could be desired. The accumulator room, which is in the basement, is 82ft. long and 66ft. broad; it will, when completed, accommodate two batteries with a capacity equal to supplying current to 2,700 lamps for 3½ hours. The cells are of the Tudor type, and are supplied by the Westphalian firm of Hagen. To the right of this compartment is a commodious boiler-house, 68ft. square and 28ft. high. The present installation comprises six boilers, all tubular, three from Babcock and Wilcox and three from Steinmüller, each of about 300 H.P. There is room for five more boilers should an extension by-and-bye be necessary. In a small compartment close to the boiler-house are three Worthington pumps for feeding purposes. The engine-room is both roomy and well appointed; the dimensions are—length 106ft., breadth 44ft., and height 36ft. There has been some little trouble about the foundations for the engines, which were not deemed sufficiently secure, and had to be reconstructed. There are three engines, all supplied by the well-known local firm of Burmeister and Wain; they are compound, with condensers. One engine is of 300 H.P., and two are of 500 H.P. The condensing water is drawn from the nearest point of the harbour through an underground concrete canal. To each engine two dynamos are coupled direct; these dynamos have an aggregate capacity of some 15,000 16-c.p. There is room for yet another pair of engines. The switchboard has its place at the northern end of the engine-house, and will occupy almost the whole wall; it can, however, be handled by one man, who will have his place on a platform some 15ft. above the floor. On the same level as this platform there is a gallery running round all the four walls of the engine-house, from which gallery there is access to the cylinders of the engines, and the gallery is also on the same level as, and connected with, the offices in the adjoining building. Except in some two or three of the main thoroughfares, where the asphalted lead cables are placed in concrete ducts, the cables (iron armature) are placed direct in the ground, with some bricks over them. The aggregate length of the cables is about 56 miles. The installation in its present form will be sufficient for about 1,400 16-c.p. lamps burning simultaneously, while the present cable system is calculated for 20,000 lamps. The buildings are, however, large enough to accommodate extensions, increasing the aggregate capacity of the installation to 30,000 to 35,000 simultaneously burning lamps. It is, however, not expected that more than 60 per cent. of the lamps installed will be alight at the same time, according to which calculation the present installation will in reality suffice for 23,000 lamps. Up to the present there are applications for about 16,000 lamps.

Another Danish town, Odense, has just got its electric central station; the matter has been started there by a limited company, and not, as in Copenhagen, by the Corporation. The installation, which is not a very large one, has been carried out by a Copenhagen firm; the cables are supplied by Callender's, of London.

An electric installation of considerable interest is the one at Hammersfest, in Norway, the northernmost town, not only in Europe, but in the world. In Hammersfest, four degrees beyond the polar circle, artificial light is naturally of great importance on account of the long polar night, which extends over 66 days. Then, again, artificial light is not wanted at all in the summer, when there is no night for 71 days. The motive power at Hammersfest is a river some two miles distant, and which, an account of the rapidity of its stream, does not freeze even in mid-winter. The electric light is installed in almost every house, and is also used for lighting the streets. It has, so far, given great satisfaction.

CORRESPONDENCE.

HISTORICAL NOTE ON DYNAMO-ELECTRIC MACHINES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Nearly 28 years ago (November, 1863), when a mere school-boy, I wrote to one whose memory will be reverenced as long as genius and goodness are esteemed—Michael Faraday. Among other questions I asked the following:—"In an ordinary magneto-electrical machine the power is derived from a steel magnet; would a piece of iron covered with wire do instead of the steel magnet, the iron to form an electro-magnet, magnetised by the magneto-electricity; the iron being first just magnetised by a battery, the future magnetisation being kept up by the current that the magnetised iron itself produces?"

The idea in my mind was, that if we started with an electro-magnet it must first of all be magnetised by an independent battery (I did not allow for any residual magnetism). This magnetisation would enable the armature coils revolving near the electro-magnet to give an electric current, which current was then to be conducted to the wires of the electro-magnet in place of the independent battery, which might now be discarded. We should thus have a magneto-electric machine with an electro-magnet (instead of a steel one); this electro-magnet being kept magnetised by the continued conveyance to it of the current produced by its magnetism in the armature coils turning close beside it. Prof. Faraday most courteously replied to my enquiries, and answered this question by a simple "No." But he added, with that characteristic modesty which was one of his greatest charms: "Your questions would require much more statement and consideration than I am allowed (by my physician) to give to any subject at present, even to researches which, being my own, are obliged to stand still."

Naturally I thought no more about the matter until I became acquainted with the results obtained in 1867, four years later, by Siemens and Wheatstone. I was then greatly interested to recognise in their results the answer to my question, and the great development of the dimly-seen idea, which had occurred to me in 1863. Had the experiment been tried, the exaltation of the magnetism of the electro-magnet, and the consequent increase of the current generated, could hardly fail to have been discovered. These results were, I believe, not foreseen, but were found out by experiment, and are the foundation of the modern dynamo.—I am, &c.,

CHAS. T. WHITMELL,
H.M. Inspector of Schools.

THE WADDELL-ENTZ STORAGE CAR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I notice in your American Notes in your issue of October 9th you speak of the Waddell-Entz Storage Car, and you mention that the batteries show a tendency towards irreversible action and disintegration when discharged at a high-current density.

We consider this a very unfair criticism. We find no disintegration of the plates even when discharging at the rate of 600 or 700 amperes per cell. In practice, we discharge at times as high as 400 amperes per cell. Our cells can also be reversed without doing the slightest injury.

We should be pleased to show your American representative these results.—We are, &c.,

THE WADDELL-ENTZ ELECTRIC CO.
W. A. Phillips.

New York, October 30, 1891.

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.]

TENDERS INVITED.—The Corporation of Sunderland invite offers for the transfer (subject to the approval of the Board of Trade) of the powers conferred upon them by the Sunderland Electric Lighting Order, 1891. Further particulars are given in our advertisement columns, and full information may be obtained from the Borough Surveyor, Town Hall, Sunderland. Offers are to be sent in to Mr. Fras. M. Bowey, Town Hall, Sunderland, before the 14th December next.

APPOINTMENT VACANT.—Our advertisement columns contain an announcement that the Corporation of Huddersfield invite applications for electrical engineers competent and willing to superintend the execution of works about to be erected by the Brush Electrical Engineering Company, for the Corporation.

SALES BY AUCTION.—This day (Friday) is the concluding day of Messrs. Wheatley Kirk, Price and Goulty's sale of new electrical fittings, dynamos, &c., &c., at 39, Queen-street, E.C. The sale includes a large quantity of various electrical supplies.

THE EXHIBITION AT ST. PETERSBURG.—Reference was made in the previous issue of *The Electrician* to the forthcoming Exhibition at St. Petersburg. This Exhibition opens on the 13th December, and will continue open for three months. In addition to the Edison exhibits mentioned in our last issue there is to be a phonograph clock, several examples of which have been seen in this country. The latest time for sending in exhibits from Great Britain was September 15th.

MESSRS. A. HALL AND CO.—This firm has recently put down the second largest installation of electric lighting in Liverpool, at the office of Messrs. Henschsberg and Ellis, University House, Islington, Liverpool. The turret of the building has been furnished with an arc lamp, the light from which is visible from the Welsh mountains, and it will doubtless form a beacon for ships entering the Mersey.

MESSRS. CHARLESWORTH, HALL, AND CO.—This firm wish us to intimate that Messrs. Morrison and Harper, of 135, Buchanan-street, Glasgow, are no longer their agents, and that all inquiries should be addressed to their works at Oldham.

LIEPMANN CARBONS.—Messrs. Nicholson, Bolton and Tyler, of 100c, Queen Victoria-street, E.C., have, we learn, purchased the stock of carbons of the late Liepmann Carbon Company, and are placing them upon the market. The plant of the Liepmann Company has been acquired by Messrs. R. Bolton and Co., of 110, Leadenhall-street, E.C.

MESSRS. H. F. JOEL AND CO.—This firm are issuing illustrated printed particulars of the Joel engine and dynamo, the Joel slow-speed dynamo, and the Joel-Pilsen arc lamp. Testimonials accompany the printed particulars.

ANGLO-GERMAN GLASS WORKS COMBINATION.—It is announced that an English joint-stock company is being formed, with a capital of £2,000,000, for the purpose of buying all the glass works in Saxony and Brandenburg. The head office of the company will be at Dresden. The proprietors of 24 works have already consented to sell, and negotiations are still pending with 20 others.

PATENT RECORD.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

APPLICATIONS FOR PATENTS.

September 28, 1891.

16,388. W. S. HAYS, Manchester. An arc lamp.

16,407. H. J. ALLISON, London. Improvements in printing telegraphs. (M. D. Porter, United States).

16,408. H. R. LOW and the Art Workshops, Limited, London. Improvements in electric arc lamps.

16,420. C. B. CALLOW, Tring. Improvements in telephone transmitters and receivers.

16,431. A. MITCHELL, London. Improvements in means and apparatus for telegraphic purposes.

16,451. W. P. THOMPSON, Liverpool. Improved system of electric train signalling for preventing railway collisions. (E. Espian and P. Ferrer, Spain).

September 29, 1891.

16,456. A. G. BROOKES, London. Improvements in electric switch apparatus, or means for controlling electric circuits. (J. P. Cushing, United States).

16,487. H. H. LEIGH, London. Obtaining a fluid for primary batteries and of recovering the effective matter from the spent fluid (J. B. Gardiner, United States).

16,522. W. P. THOMPSON. Liverpool. Improvements in or relating to electrically soldering or brazing metal. (C. L. Coffin, United States).

16,526. H. H. LAKE. London. Improvements in pencils or electrodes for electric arc lamps. (E. Tweedy, United States).

16,530. H. H. LAKE. London. Improvements in and relating to receiving instruments or relays for submarine cable and other electric circuits. (C. G. Burke, United States).

16,549. F. C. HELM. London. Fuse for electric circuits.

16,551. H. H. LAKE. London. Improvements in and relating to transmitting instruments for submarine cable and other electric circuits. (C. G. Burke, United States).

16,572. W. B. SAYERS. London. Improvements in armatures for dynamo-electric machines and motors.

September 30, 1891.

16,641. J. LEWIS. London. An improved coupling for lightning conductors.

October 1, 1891.

16,680. W. H. BLAKENEY. Glasgow. An improved electrical switch.

October 2, 1891.

16,752. D. J. MULLARKY. Bradford. An improved electrical and mechanical alarm clock.

16,767. F. W. S. JENNY. London. Improvements in apparatus for electric cooking and heating.

October 3, 1891.

16,866. A. G. MELHUISH. Peckham. A new or improved method of and means for the electrical propulsion of missiles

SPECIFICATIONS PUBLISHED.

COMPANIES' MEETINGS & REPORTS.

Western and Brazilian Telegraph Company (Limited).

The twenty-second ordinary general meeting of the Western and Brazilian Telegraph Company (Limited) was held at Winchester House, Old Broad street, yesterday, "to receive the Directors' report and the accounts for the half-year ended June 30, 1891, and to declare a dividend." Mr. W. S. Andrews occupied the chair.

The SECRETARY (Mr. R. M. Cunningham) read the notice convening the meeting and the minutes of the last ordinary general meeting, held on May 8, 1891, which were approved by the present meeting and signed by the Chairman as correct. The report of the Directors was taken as read.

The CHAIRMAN: Gentlemen, before proceeding to the ordinary business of the meeting, I have to announce with regret the resignation of one of the members of our body. It is only a couple of days old, and the first opportunity of considering it was to-day, and I have extreme regret that the gentleman to whom I allude is Mr. Henry Weaver, who has resigned his seat at the Board. Mr. Weaver seemed to think that there were certain incompatibilities in his holding the position, and with his usual straightforwardness decided to relinquish it. The Directors feel such a deep regret at losing so highly esteemed and valuable a colleague that, perhaps, they are not impartial judges. Looking at the eminent—nay, valuable—services of Mr. Weaver for the past 13 years, during times of exceptional trouble and difficulty, they cannot but deplore his loss, and wish him to feel that he carries with him their greatest regard and esteem, as well for his high character as for his undoubtedly superior qualifications as a man of business, and his estimable personality as a friend and colleague. The Directors do not at present propose to fill up the vacancy. The office might indeed be supplied, but the capacity to fill it adequately the Directors do not see their way to; and for the present at all events they have decided to go on as they are, with a united and compact body, thoroughly intimate with the complicated affairs of this undertaking. Gentlemen, that is an unpleasant duty, and it is now fulfilled. I will now proceed with the business. Notwithstanding certain disappointing elements the receipts remain, as they have been lately, of a satisfactory character; and I am pleased to say that we have again to report, as you will have seen from the figures, a very large take on the operations of the half-year. The receipts were £104,962, as compared with £89,846 for the corresponding period of last year, which, of course, is an augmentation of £15,115. With reference to that increase in money, I would remark at this stage that the increase in the traffic is considerably larger than the increase in money represents. There would have been an addition to our receipts if an endeavour that we made to establish a certain claim under our agreement with the Brazilian Submarine Company had been successful. A point was raised under that agreement. We were strongly advised upon it, so strongly in fact that the amount of the claim was included in the published estimates. In the end, however, as showing the glorious uncertainty of anything which arises, or depends, on points of law, the decision was given against us, otherwise our receipts would have been larger. At the same time, of course, that was only a claim, and the result has shown that the claim was not a good one in the opinion of those who had to adjudicate upon it. But dismissing that as something to which we were not entitled, there is a considerable diminution in our receipts, which money, so to say, we have actually earned—namely, we have made a loss on exchange during the half-year under review of £8,197. Now, you see, that is no fault of ours; but if exchange had been at par, instead of at the serious discount that it has fallen to some times, we should have come before you to-day not with an increase of £15,000 but with an increase of upwards of £23,000, and, of course, that is a very large sum of money. If a change should take place in exchange in Brazil we should benefit by it, as we did at one time. We began by losing, then we were benefiting, and now we are losing again. So much for the revenue. Now the expenditure on the whole shows a reduction of £1,871. This, of course, was spread over a number of items, some of which showed increases and some decreases. There are some 15 items in all, and six of them show increases and nine decreases: but, analysing the figures as we usually do, under Abstract A—the expenses at stations—there is, of course, an increase. There is an increase in the number of the staff. New men have had to be sent out to meet the larger business at the end of 1890, the night service introduced in 1891, and the increased work. Then, owing to the state of things in Brazil, we have had, what I am sorry to say we have rather too frequently, a number of resignations. These resignations involve replacement; and replacement, of course, involves increased expenditure. Then there is £182 increase in income-tax, which no one will object to, because it represents increased profit. There is £356 for the new agency at Buenos Ayres, £112 for travelling expenses, stationery £122, new instruments £250, and increased insurance—there being more to insure—£140. The total increase is £1,839, but there were the items I mentioned before—the nine items—which show decreases. It is not worth troubling you with the details of all these, but the result is that there is a net increase under Abstract A of £1,354, as against an increase of £15,000—or £23,000, as it would have been but for the loss on exchange—in our revenue. Under Abstract B—the ships—we show very favourably. The "Norseman" exhibits decreased expenditure of £959, and the "Viking" of £1,581. The items are really too numerous to go into in detail. The ships have been less at sea, they have used less coal, they have been less in dock, and the general expenses—upon which we always keep a very observant eye—have been reduced. The total result is a decrease of £2,540. Under Abstract C—which are the London expenses—there is a small increase of £271, of which £81 is for increased Clearing-house expenses. You all know that, to get customers, you must endeavour to be accurate, and you cannot be accurate unless you have some means of comparing your message forms at the different stations for transmission and reception in order to detect any errors that may have been made, by comparing the copies at the transmitting stations with those forwarded by the sender. That slight increase is occasioned by the increased work of that department, and there is no doubt it pays for itself a great many times over. Then, under profit and loss account, you will find that we have spent £1,344 less upon new cables for repairs. That, of course, is quite an exceptional item, but fortunately it is on the right side. Then there is a small amount paid on account of the telegraphic expenses, which really does not come into this year, for the simple reason that there has not been one. The final result of all that is an increase of revenue of £15,000, earned with a decrease of expenditure of £1,871; and but for the exchange, as I have already stated, the increase in the revenue would have been £23,000; and the extra work representing that money, you must remember, has actually had to be performed. The messages have been worked, only they have not produced quite so much; and when I tell you that the additional work performed by the staff during the past half-year represents an increase over the corresponding period of the previous year of somewhere about between 31 per cent. and 32 per cent., I do not think you will imagine that it has cost more than it ought to have cost. Of course, when we bring out a saving in expense, more work done at less expense is a *non sequitur*—it is nonsense; and therefore it is only right to point out, as I have done, that the additional expense arises under Abstract A, and that applies, of course, to all the points I have named—not merely the transmission, but also stationery, and all sorts of things that are necessary outlays in connection with the working of the traffic. I think that, on the whole, looking at these figures, you must say at least that they are not unsatisfactory. The Directors continue to give anxious attention to the expenses, and they do the best they can to keep them down. Of course, they draw the line at this—that in keeping them down they must not impair the efficiency. Therefore, if the efficiency of our work demands it, we are bound in your interest to spend such an amount of money as may be necessary. There is no doubt that judicious expenditure is really the clue to the expenses of all companies. The upshot of all this is that the gross receipts are £104,962, less working expenses £38,638, leaving a balance of £66,323. Then there was brought from last half-year £6,070; and the dividend received from the Platino Company was £7,387. We therefore arrive at the amount of £79,781. Debiting £12,866. 10s. for debenture interest, and for debenture redemption £6,233. 10s., together £19,090, we get a balance of £60,681. From this, £25,000 has been placed to reserve, leaving £35,681, out of which the Directors recommend the declaration of a dividend of 4 per cent. per annum, the same as for the corresponding period of the previous year, carrying forward £6,470. Well, gentlemen, I think that, looking at our past operations, we must have established in your minds a strong conviction as to the value of a good reserve. The shareholders have been intelligent enough and far-seeing enough from time to time to authorise these amounts being placed to reserve, and the present position is very largely owing to that. Of course that reserve is now considerably depleted. It does not stand at the present moment at the figure that it did on June 30th last. You will see in these accounts that the reserve is set down as being £254,000 odd, but since that date we have had to pay for the new loop cables. We have done that without any addition whatever to the capital account. The whole of it has been provided from the reserve, and that is why I say that you have shown your prudence in former years. The whole of that has been paid for out of reserve which you authorised us to establish. Of course, in consequence of our paying for these cables, the reserve fund stands at a lower figure. It is now £105,000, including the £25,000 that we have placed to it now, as stated in our report. We put this £25,000 to reserve for paramount motives at that time, and even if we had not had sufficiently strong motives to justify that proceeding then, I think what has been occurring within the last week, with which all you gentlemen must be acquainted, is quite justification and quite proof enough that the Board adopted a prudent course. You know that from time to time we have been threatened with competitions, and we have always made a clean breast of this matter, and told you what we were threatened with. Well, to-day we have got to go a step further. One of these competitions has been established, and the cable has been opened for traffic. The line is laid between North America and Vizeu, in Brazil; but it is not extended at the present time all the way to North America, but stops at Santiago de Cuba, and then goes over the lines of the Cuba Company, the International Ocean Company, and the American Telegraph Company. That was opened on September 1st, and I am pleased to be able to say that its effect upon our traffic was really *nil*. I do not mean to say that they did not do anything. They did something, but at all events it was not anything very considerable; and on October 22nd they had the misfortune to sustain an interruption, which still lasts. Consequently, at the present moment that cable is broken down. Of course, in the due fulfilment of time there will be, I suppose, a repair; but, as far as we can ascertain, we do not think there is any very immediate prospect of the repair being effected. Then, again, owing to the termination, most fortunately, of the Chilian war, our old competition by the West Coast of course comes into operation again. If you remember, I told you at our last meeting that our take was greatly augmented because the competing line, *viâ* the West Coast, was interrupted, owing to the Chilian difficulties, and that, therefore, we had a monopoly of the trade. After the conclusion of the war that line was re-opened. The effect of it we cannot very well estimate at present. The only guide we have is that of our receipts. You know, of course, that the receipts of late have been lower than they were at the corresponding period of last year, but then there is the apparent anomaly that our business is actually larger. We are doing more work, but are getting less money for it, and that, again, arises from the low exchange in the last half-year having become still lower this half-year. That materially affects our receipts. We should, if exchanges were anywhere near par, be presenting you with, not decreases, but increases of revenue. We hope to see that

Digitized by Google

state of things presently re-established. I have not, however, quite done with new lines. There is another line now being talked about, and some say that the cable is being made, while others say that it is not. The latter say that a cable is being made, but not for this purpose. However that may be, the thing may come forward or it may not. People connected with new companies do not always see the very great difficulties they are going to encounter, and they are apt, with syndicates and one thing and another, perhaps unknowingly, to provide means for those lines to be carried out. They suffer afterwards, not merely by the loss of their capital, but perhaps the whole of their revenue; but they contribute to raise up a lot of companies, with a lot of expenses, and in the end the public pays the expenses of two, three, or four companies, where the expenses of one company would suffice, and the work could be done by that one company with less cost than it could be done by the four companies. However, I suppose that that is too satisfactory a thing for us to hope for. I stated that this new cable, to which I have alluded, was interrupted. Now, all these cables, like the Vizeu cable, are single lines. Therefore, if one single cable is broken, the Company has no communication at all, and to that extent you will see, knowing the care with which you have duplicated your own lines, that these companies are at a decided disadvantage. Well, of course, the efforts of the Brazilian Submarine Company and of ourselves have been directed towards careful preparation for all this competition, and there is no doubt that what with our adequate skilled staff, our loop cables, our duplex apparatus arrangements, and the fact of a loop of our system being the cord line—for it is the most direct line to Brazil—any competing cable that may be laid will have its work cut out in meeting us. My own impression is that we shall be able to hold our own. We are not going to bully these people at all; we are not going to lose our tempers, or get flurried; but we think that, as men of business, if we provide with a certain amount of prescience for the future, and if we establish, as we believe we have established and are establishing, our system upon the best possible footing, with our experience, our knowledge, and with our connection, we ought at least to do considerably better than any of these gentlemen who are coming forward, knowing nothing about the whole business, and with single cables. Well, now, since our last meeting, we have carried out these great cables, these large lines, and, as I have said, we have carried them out entirely from the reserve fund. Originally, the project, if you remember, was to loop from Pernambuco to Rio; but at one of our meetings I informed the shareholders that there was a little congestion upon one of the lines between Rio and Santos, and as the strength of a line and the capacity of a line are that of its weakest link, of course it became very desirable to do away with that link. For that purpose the loop was extended on from Rio to Santos. These lines have rendered extremely good service. The duplex is being extended, and if we have been strong hitherto, I think we shall be a great deal stronger now. Then, of course, it must be remembered that these loops, quite apart from their incidence as affecting competition, are guarantees to a large extent of your revenues. At one time where you had single lines, and where they became interrupted, the losses, as you know, were very great. Your liability now to total interruption is enormously lessened, and, consequently, you are not so likely as you were before to sustain those serious losses of traffic and of revenue. At the last meeting, or the previous one, you authorised the acquisition of the undertaking of the Montevidean Telegraph Company. It was acquired for a payment in shares by this Company, and the purchase price shows us 5 per cent. upon it. Previously to our purchasing it it held a charge upon our gross revenue of so much. Consequently we have substituted dividends on shares if they are earned for a charge upon revenue which must have been paid under any conditions. At the same time, we believe that this is a very good substitution for the Montevidean people, because they were given the benefit of the expenses they were paying, and they get a fair return. The effect of that—to harp on the old string—is to give us increased strength. There was before a separate Board coming on to this link, and we have got rid of that link, and the Montevidean Company is absorbed and has become a part of this Company, with all its cables. Gentlemen, there has very frequently been discussion about some reorganisation of our debentures. Well, a scheme had been prepared with this object. The lawyers were satisfied with it, and said that it avoided all the difficulties, and certain terms could have been carried out; and I did expect to be able to come before you to-day, and to tell you that we were going to launch this scheme; but meanwhile we received a communication from Brazil which has compelled us to pause in your interest for the time being. Of course, that does not affect the merits of our scheme, and does not emanate from debenture holders. I would go into detail, and tell you what the communication is if it were altogether judicious to do so. I do not, however, think that it is, but if any shareholder would like to have the information, it shall be placed fully at his disposal if he will be good enough to call at the offices of the Company. Owing to the competition to which I have alluded, you will observe that there is a cessation in the publication of our weekly traffics. The Brazilian Submarine Company took the step of stopping their publication—I confess I think wisely. I have been of opinion personally that it ought to have been stopped before. (No, no.) Pardon me, I think you will admit, when I say a few more words, that there is a great deal to be said on both sides. I should preface these observations by saying that in the abstract, as I have already told Mr. Fry, we are always in favour of the publication of these traffic returns. The best proof of that, perhaps, is that we have published them. I do not know what better proof I can give you than that; but when you find yourselves threatened with competition, is it a wise thing, week by week, to give these gentlemen full information of the value of the traffic that is being transmitted for which they are working to get a slice? I do not think it is (hear, hear; "Quite right.") Therefore, in conjunction with our partners, who we think acted wisely, we should probably have done the same thing if they had not, and have proposed it to them, the publication has been stopped. I think there is nothing further for me to mention now, and, therefore, with your permission, I will propose—

"*That the report and accounts for the half year ended June* 30, 1891, *as submitted, be and the same are hereby approved and adopted, and that a dividend for the half year ended June* 30*th at the rate of* £4 *per cent. per annum be and is hereby declared payable on the* 13*th inst.*"

I beg to move that resolution, and after it has been seconded I shall be very happy to reply to any questions as far as I can.

Mr. C. W. EARLE seconded the resolution.

Mr. ENNIS asked whether the Chairman had made any reference to the sum mentioned in the second paragraph of the Directors' report of £11,121. 4s., paid in respect of traffic receipts between March, 1889, and December, 1890, hitherto under dispute.

A SHAREHOLDER inquired whether the question had been considered of getting rid of one or both of the Company's ships now that they had duplicated their cables. They had got the new cable referred to on a former occasion, but they now heard nothing further as to what was to be done with the ships, the cost of which was about 1½ per cent. on their share capital, which was a tremendous amount. Of course, they would not save the whole of this amount if they got rid of the ships, for they would have some work to do, which would have to be done by other ships. The question, however, was what would pay best.

The CHAIRMAN: I have very much pleasure to repeat, in reply to the first gentleman, as nearly as I can, the observations I made with regard to the sum he mentioned. That arose under a claim with the Brazilian Submarine Company. We were advised that the claim was good—in fact, we were so strongly advised that the amount was included in our estimates, but when the matter was tried out the claim proved not to be a good one, but a bad one. That £11,000, therefore, which was included in our estimates, but which never really belonged to us, had to be knocked out. With reference to the ships, one of the main reasons for the retention in our service of a large ship—a larger ship than might otherwise have been necessary—has been the fact that some of your cable was in deep water. I did not refer to that, because, though it is mentioned in the report, it does not properly belong to the half-year under review. As a fact, we had 200 miles in very deep water, and that old, unsuitable type of cable remaining—which was a legacy from the former Board to the present Directors—has been gradually renewed out of the system, so to say; and at the end of September or thereabouts—as recently as that—we removed the last section of this unsatisfactory stuff. We substituted for that 200 miles a certain length of new cable, a certain length—some 50 miles surplus—from the expedition to lay the loops, and the remainder was made up by stock. That led us—though there had not been time hitherto for it to do so— to a decision with respect to this particular ship, and consequently to what we have told you has been in our minds all along - the question of some substitution. Now, I may tell you that we have had in the office of the Company—although we have not been in a position to proceed with the matter, on account of that section which is still in very deep water—plans for a new ship, which would be a cheaper vessel to work than the "Norseman"; and now that that old cable is out of the system, we have already considered the matter, and we shall not merely consider it, but we shall come to a decision very speedily upon the question that has been brought forward. Whatever we do in regard to it, we shall, of course, do with a full sense of our responsibilities for the maintenance of your system, which is and must be paramount to us. That has been the first consideration up to the present time. As I say, there is a modification in it now—quite a recent modification—which will admit of further consideration being given to the matter, and that will be done.

Mr. W. GRIFFITH observed that the very able and lucid speech of the Chairman had answered most of the questions that might have suggested themselves to the shareholders. In his remarks, however, the Chairman had stated that the expenditure of the Company had been somewhat increased by resignation of their servants. This did not refer to Mr. Weaver, whose resignation they all deplored; but it was regrettable that they were losing certain gentlemen who were tried and experienced, and more especially was it regrettable on account of the great expense of obtaining successors. He therefore desired to ask whether any plan could be devised by which the Company could retain in their service such gentlemen as those to whom the Chairman had alluded.

A SHAREHOLDER said he was convinced that they would all deeply regret the Chairman's announcement of the resignation of Mr. Weaver. From the very commencement of submarine telegraphy, Mr. Weaver had been one of the principal Directors of submarine cables, and they must all greatly deplore his loss. The Chairman's speech must, he thought, be received by all the shareholders with great satisfaction, considering the latest information they had had from their colleagues, the Brazilian Submarine Company. At the meeting of that Company, the Chairman gave—in, as he (the speaker) thought, rather an extraordinary manner—a most pessimistic view of the position. What applied to that Company also applied, he thought, to the Western and Brazilian Company, and he was therefore sure, from the lucid statement just made by the Chairman, that the shareholders would go away with the idea that if they were going to have all the trouble which was anticipated they would not be wiped out, but would be able to exist and to hold their own. With reference to the question of the publication of the traffic return, in an interview which he had recently had with the Chairman he (the speaker) had stated that he was quite willing to fall into the views of the Directors. If the Chairman thought it necessary that the traffic receipts should not be published, he, as a large shareholder, was perfectly willing to trust them. He thought that up to the present time the shareholders had had every confidence in the manner in which the Chairman had carried out the policy of the Board and also with the results obtained; but, at the same time, he

Digitized by Google

trusted that he was not saying too much when he said that if in the future they should receive suggestions—recommendations—from their colleagues of the Brazilian Submarine Company, they would, as a Board, not be too subservient to the views of those gentlemen. They were entirely an independent Company, and did not want to be under the thumb of the Brazilian Submarine Company. They were willing as their colleagues to agree with them and run with them in everything that was reasonable. He trusted that if the competition should come to an end—and perhaps it might never do so—they might see their way again to publish the weekly traffic returns. If they were to have very bad returns, no one was more entitled to know the fact than the shareholders. If they were going to have good traffics—and this was what they desired to keep away from their opponents—he was perfectly willing that the traffics should not be published, and to leave the matter entirely in the hands of the Directors.

A SHAREHOLDER asked whether the information respecting the receipts of the Company would be denied to shareholders who applied at the office. The matter opened up another question altogether, which he did not want to mention there, but it was a subject upon which he would like to hear some expression from the Chairman.

The CHAIRMAN: I think that when the Directors desire, as an abstract question, to give every publicity to the traffics, such publicity, if given at all, must be complete. I do not think it would do for Directors to give to gentlemen applying at the offices this information, because you then have to define what is a *bona fide* shareholder; and I should hardly like to undertake the job.

A SHAREHOLDER stated that he observed in the present balance sheet the sum of £154,000 set down as the expenditure upon new cables, whereas in 1888 the Chairman mentioned as an estimated item £90,000. This was so wide a difference that he would like an explanation upon the point.

The CHAIRMAN: The original reference was made to the cable which was ordered for Brazil, but which we were not allowed to lay. The Government, as you remember, at that time and for some time afterwards was against us. That section of the cable was laid upon another part of the system, and it represents only a small part of the total scheme which has since been carried out.

A SHAREHOLDER observed that it was stated that debentures to the amount of £50,000 would be issued for the new cables.

The CHAIRMAN; Originally the question arose how the funds were to be provided. An unexpected amount of money was earned in one half year; there was a very large balance, and there was a sum of about £26,000 which the Directors, with the shareholders' approval, did not divide in dividends, but recommended the shareholders to put to reserve fund. That £26,000 was, therefore, so much to the good. The reserves have since been satisfactory, and with the approval of the shareholders, I think the Directors have not issued that £50,000 of debentures. We have the power to do so, and that is a nest egg should it be necessary; but if we can avoid it, and manage to build up this reserve fund again, why should we put before the shareholders £2,500 a year if it is not absolutely necessary to do so? (hear, hear.) In reply to the question asked by Mr. Griffith, it is not alone the skilled and the best men who leave us. The old servants remain with us as long as they can, but a great many of the new men who go out, not being acclimatised—and there have been two or three very bad seasons in Brazil—have suffered quite exceptionally; and, not to put too fine a point on it, got "funky" and came back.

A SHAREHOLDER enquired whether any of the staff had gone to the competing companies.

The CHAIRMAN: None as far as I know.

A SHAREHOLDER asked if the £11,000 mentioned in the second paragraph of the Directors' report came out of their total earnings, and whether these earnings had been £104,000 or £116,000?

The CHAIRMAN: The gross earnings are £114,000. The other amount was a claim which was not substantiated, as I have already mentioned. He then put the resolution to the meeting in the usual manner, and declared it carried unanimously, adding that that concluded the business.

Mr. GRIFFITH said he thought the shareholders ought not to separate without tendering their thanks to the Chairman and his colleagues. They were very fortunate at the present juncture in having men of experience at the helm of affairs.

A SHAREHOLDER, in seconding the motion, expressed his conviction that no shareholder would be more pleased to read the Chairman's speech on the following day than the shareholders of the Brazilian Submarine Company.

The resolution was carried unanimously.

The CHAIRMAN: On the part of my colleagues, and on my own part, I beg to thank you for your kind vote, and the manner in which it has been received.

City of London Electric Lighting Company (Ltd.).

An extraordinary general meeting of this Company was held at Winchester House, Old Broad-street, E.C., on Thursday last week, at 3 p.m., Sir David Salomons, Bart., in the chair.

The SECRETARY (Mr. J. Cecil Bull) having read the notice convening the meeting, the following resolution was proposed by the CHAIRMAN, seconded by the EARL of SUFFOLK, and carried unanimously:—

"*That the special resolution which was passed at the ordinary general meeting of the Company held on the 15th day of October, 1891, as follows:—That Article No. 13 of the Company's Articles of Association be altered by inserting after the words 'each call,' at the end of the fourth line, the following:—'and that no call shall exceed one-fifth of the nominal amount of a share, or be made payable within two months after the last preceding call was payable,' be and is hereby confirmed.*"

The CHAIRMAN intimated that this really concluded the business of the meeting, but before separating he would like to say a few words in answer to an assertion he had seen in certain newspapers that he had conveyed an entirely erroneous impression as to the relative cos. of gas and electricity. He said: I will first state that an 8 c.p. glow lamp is usually taken to replace a 5ft. gas burner at usual gas pressure, the light in each case being approximately equal. Again, an 8 c.p. lamp requires from 30 to 33 watt-hours (*i.e.*, ampere × volt hours), and as a Board of Trade unit equals 1,000 amperes × volt hours, it consequently results that at 8d. per Board of Trade unit the cost of 33 8 c.p. lamps for one hour comes out at 8d., if the value of the lamps is excluded. This is arrived at by dividing 1,000 by 33, giving approximately 33·8 c.p. lamps for one hour for 8d. Now, glow lamps are said to last over 1,000 hours before renewal, but in practice they last much longer. We will, however, take the 1,000 hours, and as each lamp costs 3s. 6d., or 168 farthings, then the cost of wear of 33 lamps for one hour is 168/1000 × 33 = 6 farthings, or 1½d.; consequently, the cost of one Board of Trade unit becomes 9½d. when wear of lamps is taken into account: 1 8 c.p. lamp for one hour = 9½d./33 = 1·15 farthings = 1¼ farthings.

Gas being reckoned by price per 1,000 cubic feet, a foot burner consumes 5/1000 = 1/200 of charged price per 1,000 cubic feet. Consequently, with gas at 2s. 6d. per 1,000 cubic feet, a 5-foot burner costs per hour, 1/200 × 2s. 6d. = 120/200 farthings = 3/5 = 0·6 farthing. Gas at 3s. per 1,000 cubic feet, by a similar calculation = 1/200 × 3s. = 144/200 farthings = 0·7 farthing. Gas at 3s. 6d. per 1,000 cubic feet similarly = 1/200 × 3s. 6d. = 168/200 farthings = 0·84 farthing. Gas at 4s. 6d. per 1,000 cubic feet, also by same method = 1/200 × 4s. 6d. = 216/200 farthings = 1·08 farthings. Gas at 5s. per 1 5-feet burner for one hour costs 1/200 × 5s. = 240/200 farthings = 1·2 farthings.

From these calculations it will be seen that the electric light in point of cost lies between gas at 4s. 6d. and 5s. per 1,000 cubic feet; the actual value being over 4s. 10½d and under 4s. 11¾d.

No questions being asked, the meeting then terminated.

West India and Panama Telegraph Company (Ltd.).

The following is the report of the Directors for the half-year ended June 30, 1891, to be submitted to the twenty-ninth ordinary general meeting, to be held at Winchester House, Old Broad street, E.C., on Tuesday next, Nov. 17, 1891, at 2 p.m.:—

The Directors submit the accounts for the six months ended June 30, 1891. The amount to credit of revenue is £47,641. 16s., against £52,351 2s. 4d. for the corresponding half-year of 1890; and the expenses have been £24,868. 16s., against £26.619. 17s. 4d. for the same period in 1890, leaving a balance of £22,773. which, with the balance of £668. 3s. 2d. brought from last account, makes a total of £23,441. 3s. 2d. Of this sum the Directors have placed £2,000 to reserve, leaving an available balance of £21,441. 3s. 2d., with which it is proposed to deal as follows:—First preference shares—dividend, six months to June 30th, 6s. per share, £10,368. 18s.; second preference shares—dividend, six months to June 30th, 6s. per share, £1,400. 14s.; ordinary shares—1s. per share (free of income tax), £4,416. 1s.; balance to current half-year's account, £5,255 10s. 2d.

The traffic receipts for the six months show a decrease of £4,598. 2s. 3d. as compared with the corresponding period.

The expenses for repairs to cables amount to £11,936. 14s. 2d., being £1,999. 14s. 1d. less than those for the corresponding half-year, owing to fewer interruptions.

The shareholders have been informed from time to time of the impending competition of the Société Française des Télégraphes Sous-Marins. This competition assumed an active shape in the early part of June, when that Company's cable was extended from Porto Plata (San Domingo) to the two French colonies, Martinique and Guadeloupe. The rates to and from Martinique and Guadeloupe were reduced by the French Company, and the West India Company also found it expedient to reduce its tariff to the more distant colonies, where, owing to the geographical position, the tariff is necessarily higher than in the more northern islands. These reductions have entailed considerable losses of revenue, and, owing to the marked depression of West India trade during the past few months, there has been not only no increase in the volume of traffic consequent upon the reduced rates, but an absolute falling-off in the number of words transmitted. It is, however, anticipated that this trade will revive next year, as the prospects of the coming sugar crop are encouraging.

In view of the circumstances stated above, and of the large expenditure in repairs during the current half-year, the Directors have deemed it prudent to carry over a larger balance than usual to the next account.

The Company's s.s. "Grappler" is now engaged in laying the new cable between Trinidad and Demerara.

A contract has been entered into with W. T. Henley's Telegraph Works Company for the manufacture and shipment of 250 nautical miles of deep-sea cable for stock.

Woodhouse and Rawson United (Limited).

The following is the annual report of the Directors to be presented to the shareholders at the general meeting to be held at Cannon-street Hotel, London, E.C., to-day (Friday), November 13, 1891, at 12 o'clock.

The Directors present herewith to their shareholders the report and balance sheet for the past year. Of the second issue of capital authorised at the last general meeting, namely, 20,000 ordinary shares, 10,000 preference shares, and 100,000 £5½ Debenture Stock, 9,889 ordinary shares, 7,000 preference and £85,192 Debenture Stock have been allotted. The balance sheet shows a net profit of £35,103. 9s. 2d., which, with the sum of £16,335. 15s. 3d., the amount brought forward from last year, makes a total of £51,439. 4s. 5d. Out of this sum the Directors paid, in February last, an interim dividend at the rate of 8 per cent. upon the preference shares, and 15 per cent. upon the ordinary shares, and they now recommend a further dividend up to June 30th last at the same rates.

Digitized by Google

These payments will absorb the sum of £30,507. 16s., and leave the sum of £20,931. 8s. 5d. Out of this balance the Directors recommend the appropriation of £10,000 to the reserve fund, which will then stand at £35,000, £1,500 to bad debt reserve, and the addition of £500 to the *employés'* pension fund, bringing this up, with interest, to £1,565, and leaving £8,931 8s. 5d. to be carried forward to the current year's account. With a view of enabling the balance sheet to be prepared up to as late a date as possible, the accounts for all the branches are made up to May 31st, stock being taken to that date, whereas the head office accounts are made up to July 31st.

West Kensington Hall, Hammersmith.—During the last year these works have been increased by the erection of a large new factory, 133ft. by 44ft. and five storeys high, fitted with all the latest appliances. The old engines and boilers have been replaced by those of the latest and most efficient type, the old chimney has been pulled down, and a large one erected, whilst the foundry has been enlarged, and the works generally improved. The cost of the new buildings has been put to capital account, whilst of the cost of moving, £2,000 has been written off revenue account. Although alterations have not been carried out without considerable interruption of the work in hand, the turnover has largely increased, and it is hoped that this extension will enable the Company satisfactorily to keep pace with the work offered in this department. The power for the whole of the new factory is transmitted by electric motors placed on the different floors. One of the Company's buildings has been fitted up for the manufacture of the Epstein accumulator, one of the inventions mentioned in the report of last year as being tested, and which has more than borne out the expectations that had been formed of it.

Union Foundry at Kidsgrove.—These works have been consolidated, a new boiler-shop erected, and new plant put down. The mortgage which was existing on the property when it was taken over has been substantially reduced. The works are at present very busy, and there is every prospect of a considerable development of trade in the future. An extension of this branch has been made by the acquisition of the business of Messrs. Anderson and Gallwey, hydraulic engineers, for whom the Company had been manufacturing, and who have a large number of specialties in hydraulic machinery now taken over by the Company. Mr. Gallwey remains with the Company as manager of this department. The patents of Mr. Reginald Bolton for electric cranes and winches have also been purchased, and promise to bring in a considerable amount of valuable business.

Cornbrook Telegraph Works.—These works at Manchester have been extended by the erection of special plant for the manufacture of dynamos and motors, the works having had hitherto a difficulty in supplying the orders in hand.

Supply Department.—This important department has continued to increase rapidly, the turnover for the last year having considerably exceeded that of the previous year, and the net profit has doubled. The increase has been such as to necessitate a wharf being leased for the heavier goods—viz., Lyon's Wharf, Thames-street, E.C. This increase since the date of the balance sheet has been maintained. The acquisition of the new warehouse and showroom is giving satisfactory results.

Installation Department.—A large number of contracts have been carried out, and at the present time the amount of work in hand is larger than at any previous period. Amongst the contracts at present in hand is one for the erection of electric lighting plant for public lighting in the streets of Johannesberg. The central station plant supplied by the Company for Barcelona is working thoroughly satisfactory.

Bradford Branch.—This portion of the business, from whence the installation work in Yorkshire is carried out, has given progressive results, and the supply of goods in the North is being now dealt with from that centre.

With regard to the department for testing and proving of new patents and inventions, to which your Directors drew attention in their last report, and at the general meeting, as likely to add materially to the profits, a large amount of business has been offered and examined. Out of the four important electrical inventions undergoing process of testing, mentioned in the previous report, only one has turned out sufficiently well to justify this Company in introducing it to the public, this being the Epstein accumulator, to acquire and develope which the Epstein Electric Accumulator Company (Limited) has been formed, with Mr. Epstein as Managing Director, and from which this Company looks for important pecuniary results.

Out of other new business in course of investigation by your officials, one, after close examination by your Managing Director, has turned out satisfactorily, and gives promise, on its introduction by your Company at an early date, to command great attention.

The Directors feel themselves justified in alluding to the various Elmore Copper Depositing Companies that have been introduced to the public under the auspices of your Company. As the technical statements made have been proved by actual results, your Directors not only believe that the several Companies will fulfil the expectations held out by us, but will exceed them, and they have therefore entertained proposals for a further development of the process in other countries at an early date.

The sum of £75,000, lodged by Woodhouse and Rawson, Limited, with this Company as guarantee fund for the payment of a minimum dividend of 15 per cent. per annum up to the 30th June next, has been repaid that Company, under the authorisation given to that effect at the last general meeting.

Under the articles, two Directors retire, Mr. Samuel Pope, Q.C., and Mr. Philip Rawson, who being eligible offer themselves for re-election. The auditors, Messrs. Pixley and Co. (now Messrs. Jackson, Pixley, Husey and Co.), retire according to the articles, and offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

BENFIELD (LIMITED).—This Company was registered on November 4th, with a capital of £50.000 in £10 shares, by Jordan and Sons, 120, Chancery-lane, W.C. The objects are to acquire and carry on the business of "horse shoe manufacturers, blacksmiths, iron and brass founders, boiler makers, mechanical and electrical engineers, &c.," carried on by Benfield and Co., at Walsall, Staffordshire.

CONCENTRIC SEAMLESS STEEL TUBE COMPANY (LIMITED).—This Company was registered on November 5th, with a capital of £20,000, in £5 shares, by Beale and Co., 28, George-street, Westminster. The objects are :—To carry on the business of tube manufacturers, carried on at the Dartmouth Works, Dartmouth-street, Birmingham, by G. J. Rossiter, and to carry on the business of manufacturers of weldless steel tube for locomotive, marine, and other boilers, hydraulic presses, boring rods, spindles, torpedoes, &c. The first Directors are G. J. Rossiter and G. W. Holt.

EAST COAST ENGINEERING COMPANY (LIMITED).—This Company was registered on November 4th, with a capital of £2,000 in £10 shares, by R. B. Nicholson, Lowestoft. It intends to carry on the business of mechanical and electrical engineers, founders, land, marine and gas engine manufacturers, dealers and repairers, manufacturers of heating apparatus, &c. Registered without articles of association.

GLOBE ELECTRIC COMPANY (LIMITED).—This Company was registered on November 4th, with a capital of £10,000, in £1 shares, by Messrs. Gover and Chiles, 71, Queen-street, Cheapside, E.C. Its objects are :—To acquire by purchase, lease or otherwise, or to improve, manage, work, develop, sell or otherwise deal with property of all kinds, and in particular electrical and mechanical engineering businesses, including chemical engineering, electrical and other works, &c. The number of Directors is not to be less than three nor more than five, the first to be nominated by the subscribers to the memorandum and articles of association.

SECTIONAL STANDARDS (LIMITED).—This Company was registered on November 3rd, with a capital of £3,000 in £10 shares, by Wood, Bird and Wood, 16, Eastcheap, E.C. The objects are :—To acquire and develop an invention of improvements in telegraph poles. The first Directors are Messrs. F. H. Lloyd, F. N. Cowell, and F. W. Drewitt.

BRITISH ELECTRIC INSTALLATION CONTRACTORS (LIMITED).—The first registered office of the above-named Company, which was registered on October 12th last with a capital of £20,000, in £5 shares, is situated at 1, Angel-street, Worcester (filed on November 7, 1891).

BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED).—The registered office of the above named Company has been removed from 112, Belvedere-road, Lambeth, S.E., and is now situate at the Albert Buildings, 49, Queen Victoria-street, E.C.

GORDON ELECTRIC TRACTION COMPANY (LIMITED).—The statutory return of this Company, made up to December 24, 1890, was filed on November 5, 1891. The Company was registered on August 13, 1890, with a capital of £2,400, in £10 shares, to acquire and develop the invention of John Gordon of a system of electric street-car traction, for which provisional protection was granted May 5, 1890, and numbered 6,083, and to carry on experiments at Messrs. Merryweather and Sons' works at Greenwich, for the purpose of showing the value of the invention. John Gordon was allotted 60 shares in consideration for the said invention, and was appointed Managing Director, with a salary of £4 per week. At the time of the making up, 172 shares had been taken up, of which 60 were considered as fully paid. Upon the remaining 112 the full amount was called, and £860 paid, leaving £260 unpaid. The principal shareholders are J. Gordon, of 13, Nettleton-road, New Cross, electrical engineer (52 shares), and W. Lüttge, of 17, Gracechurch-street, E.C. (36 shares), Registered office: Messrs. Merryweather and Sons' offices, Greenwich-road, Greenwich S.E.

OGMORE VALLEY ELECTRIC LIGHT AND POWER SUPPLY COMPANY (LIMITED).—The statutory return of the above-named Company, made up to October 22nd, was filed on November 4, 1891. The Company was registered on June 10, 1891, with a capital of £10,000 in £5 shares, to supply the Ogmore Valley, in the county of Glamorgan and neighbourhood, with electric light ; 569 shares have been taken up, upon all of which £1 per share has been called, and £434. 10s. has been paid, leaving £134. 10s. unpaid. All the shares have been taken up locally. No agreements for the acquisition of works, plant, contracts, &c., have as yet been filed. Registered office : 2, Wyndham-villas, Nantymoel, near Bridgend, Glamorganshire.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts of this Company for the week ended November 8th amounted to £783 ; aggregate receipts for half-year to date, £13,546.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED). Notice is given that on Thursday, November 19th, will be drawn 312 Five

Digitized by Google

per Cent. Mortgage Debentures of £100 each, for payment on Jan. 1st, 1892. The drawing will take place at the Company's Offices, 50, Old Broad-street, E.C.

METROPOLITAN ELECTRIC SUPPLY COMPANY (LIMITED).—Application has been made to the Stock Exchange Committee to allow the additional shares Nos. 101 to 6,100 of this Company to be quoted in the Official List.

SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—The accounts of this Company for the year ended September 30, 1891, have been passed, and, subject to audit, the Directors recommend the shareholders to declare a dividend at the rate of 6 per cent. per annum for the six months ended September 30 last, and of 5 per cent. for the twelve months ended at the same date, making, together with the interim dividend declared in May last, a total dividend for the year of 11 per cent.

WEST COAST OF AMERICA TELEGRAPH COMPANY (LTD.).—The traffic receipts of this Company for the month ended October 31st were £3,000.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LTD).—The traffic receipts of this Company for the half-month to October 31st were £1,990, as compared with £2,741 in the corresponding period of last year. The June receipts, estimated at £4,755, realised £4,503.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 705.—Vol. XXVIII. FRIDAY, NOVEMBER 20, 1891. PRICE FOURPENCE. *Annual Subscription (U. K.), 19/6.*

NOTES.

The application of the City of London Electric Lighting Company for an extension of one year in the time of their street-lighting contract, which is recorded in our "Notes" columns, appears by all accounts to have excited rather a strong expression of feeling on the part of those present at Tuesday's meeting of the Commissioners of Sewers. The *City Press* refers to the petition as a painful surprise, and states that the text of the communication caused considerable indignation, and talks of "the vexatious delays which have already occurred in the electric-lighting operations within the City."

The present Company can, we doubt not, make out an excellent case for itself. It only came into existence in July last; the consent of the Board of Trade and of the Commissioners of Sewers to the latest transfer of contracts was only obtained at the end of August; there has been tightness in the Money Market; the Pioneer Company could not be expected to involve itself in a large outlay until the financial success of the existing concern was assured; the work is one of considerable magnitude and some difficulty; everything is *now* being done to make up for lost time; the extension asked will probably never be taken advantage of. All this may be urged, but the broad fact remains, and alone interests the public, who cannot be expected to follow intricate company evolutions or realize why the running of a few hundred arcs should be the cause of so much pother—that although the contract for the Central District was signed on December 3, 1889, and that for the Eastern District on January 28, 1890, yet so far the only outward and visible signs are the 26 arc lamps in Queen Victoria-street. We cannot but think that this application for still more time is to be regretted.

Just as we go to press we hear that at last, after protracted "interference," lasting since 1877, the United States Patent Office has issued the microphone patent; but whether to Berliner or to Edison the press cablegram does not say. In either case the affair is the property of the American Bell Telephone Company. The granting of a patent for the microphone thirteen years after its discovery is certainly a grotesque proceeding, according to our insular notions; but, fortunately, it is a purely local custom. The American microphone monopoly has now a fresh lease of seventeen years.

Another and a similar telephone patent "interference" case is also apparently drawing to a conclusion. According to the *Electrical Review* of New York, Commissioner Simonds, of the American Patent Office, on October 25 rejected an appeal from a decision of the Board of Examiners-in-Chief in connection with the Drawbaugh patent. This question has been in a state of litigation for more than eleven years. The Commissioner found that the improvement in controversy "was in public use and on sale for more than two years" prior to Drawbaugh's application.

The Blackpool Tramway continues to be the best evidence that we have in this country that electric traction can be made to pay. It again pays a dividend of 7½ per cent. on its paid-up capital of £20,000, and adds a relatively substantial sum to the reserve fund, which now stands at £6,000. The number of passengers carried since the last report has been 933,692, or nearly 15 per cent. more than last year, the car miles run being 98,000, as against 92,000, an increase of only a little more than 6 per cent. The figures put down for conduit, and for motor and gear repairs seem very reasonable, viz., £144 and £192. There are now 12 cars running, so that the latter figure comes out at only £16 per car, which is about 5 per cent. of their cost, and about 13½ per cent. of the original cost of the complete electrical fittings.

Most of our readers who visited Frankfort Exhibition saw the experiments of Dr. Frölich which were shown in Messrs. Siemens and Halske's Court, and which brought before the eye in a very pleasing manner an optical reproduction of the current curves in certain cases of current flow in conductors and condensers. We publish this week a short account of these experiments, and it will be seen from this that to obtain this optical reproduction of the current curves, a telephone is used having a mirror on its diaphragm, after the fashion of Prof. Perry's steam indicator. These curves show curious oscillations and wavelets superimposed on the main curve. It might be thought that these were due to oscillations of the current. A study of Dr. Frölich's Paper, however, will show that the superimposed wavelets are really due to the natural period of vibration of the telephone diaphragm, and that they are of the nature of a defect in the means of observation, just as the effects of vibration of the spring in an ordinary steam indicator diagram disturb the true curve due to variation of steam pressure alone. It does not appear as if we had as

Digitized by Google

yet a means at our disposal of rendering visible, by an optical method, the true form of a current curve, and that when accuracy of determination of the form of an alternating current wave is essential, the methods of determination of instantaneous values, such as described by Dr. Louis Duncan in our present issue, or such as have been employed by Prof. Ryan and many others, are to be preferred.

We are sure that no letter from Mr. Crompton, especially when it deals with so important a question as the use of electric motors, will fail to receive the most careful attention of our readers. In the communication which he sends this week he says that "the first question put by an intending user of a labour-saving appliance is not what will be the cost of power and attendance required to run it, but what will be its first cost, and in what time may he expect to repay this first-cost by the economy it introduces." We would go farther and suggest that many small concerns will think even more about the first cost than about the saving. A copper kettle is cheaper in the long run than a tin one, but this economy becomes a luxury on account of its first cost. We welcome this point, which was not considered in our recent article, and hope that it may materially assist the sale of motors. As to the cost of running, Mr. Crompton's figures are very interesting; but they go to prove our contention that it is *only in so far that the work is intermittent* that a small motor is cheaper than a gas engine; and this saving will be inversely proportional to the load factor, but there is a balance of several pence to make up before the saving becomes positive. The concluding remarks about superseding line shafting by separate motors touches a totally different but extremely inportant matter. We look forward to a great development of this system, which gives much satisfaction wherever it has been tried.

Is an apology needed for alluding to a "magnetic lady" in these columns? To describe all her tricks would, indeed, be out of place here, but they are fully set out in the London papers of this week. Anything magnetic concerns us; and anything alleged to be magnetic at least deserves comment, whether it be a fraudulent electropathic belt, or a mistaken and hence a misleading use of the term. The performance at the Alhambra on Saturday afternoon last was extremely interesting to those who were invited to witness the experiments; and though it may be a pity that some sort of tests, mechanical, not to say scientific, were not made, it can hardly be expected that they would be allowed. A "committee" was selected from the invited audience. About twenty persons went on the stage; but only one face was known to us, viz., that of Mr. J. B. Verity. In him the electrical trade was adequately represented. The last name, not on the list, but on a visiting card, apparently self-invited, was that of the notorious electropathic quack, in whom electrical science may be said to have been thoroughly misrepresented.

We had an excellent opportunity of seeing the performance, but failed to see any evidence whatever that any force was being exerted beyond the fact that there was a good deal of apparent struggling, puffing, and redness of face on the part of those who took part in the experiments. When a strong man is learning to ride a bicycle or to skate he expends an enormous amount of force, but nine-tenths of it is misplaced and mysteriously disappears; he is thoroughly tired after an hour, during which he has done no more work than a child could do in a few minutes. Before devoting any more space to this matter we want scientific evidence that any considerable force is exerted. A spring balance would do, or a definite and measured deflection of a cue. The bare arm is of course a mere blind to avoid such a test; but let the man who thinks that he is lifting stand on a weighing machine. If he adds Mrs. Abbott's weight to his own, we will open our columns to a discussion on the matter. We will not question Mr. Verity's acquaintance with the Alhambra stage, but it is surprising that with his commercial abilities he should expect that the manager would allow any real test to be made.

Owing to pressure on our space we have been obliged to hold over our New York correspondent's letter until next week.

Prof. Rücker.—The Royal Society has awarded Prof. Rücker one of its Royal Medals for this year.

St. George-the-Martyr Vestry.—This Vestry has agreed to consent to the Provisional Order of the County of London Electric Lighting Company.

Crystal Palace Electrical Exhibition.—Mr. Musgrave Heaphy has been appointed to supervise the various installations, as far as fire risk is concerned, during the forthcoming Electrical Exhibition.

The Fire at Messrs. Laing, Wharton and Down's.—The many friends of this firm will be sorry to learn that a serious fire occurred at their Works last Tuesday night. Arrangements are, however, being made to execute orders as promptly as ever.

The Determination of Currents in Absolute Electromagnetic Measure.—In the issue for November 13th the following foot-note was omitted from the right-hand column of page 34:—"In order to make Figs. 32 and 33 harmonise, in Fig. 32 P should change places with Q and P′ with Q′."

Glasgow.—The Glasgow Town Council on Thursday last week discussed the question of taking over the whole of the tramway system within Greater Glasgow, and resolved by 50 votes to six to take over all the lines on the termination of the lease, two and a half years hence.

Royal Society.—The following Papers were down for reading yesterday before the Royal Society:—"The Thermal Emissivity of Thin Wires in Air," by Prof. Ayrton, F.R.S., and H. Kilgour; "On the Time Relations of the Excursions of the Capillary Electrometer," by G. J. Burch.

Hammersmith Vestry.—At the last meeting of this Vestry the application of the Putney and Hammersmith Electric Light and Power Supply Company was referred to the Electric Lighting Committee. It was also decided to hold a special meeting of the Vestry on December 9th, to consider the Committee's report.

Cable Communication in the Indian Ocean.—Alluding to the terrible damage done by a recent cyclone in India, the Calcutta correspondent of the *Times* says:—The disaster has again brought into prominence the necessity of laying telegraph cables to the Andamans. The want of such cable is the greatest defect in the Bay of Bengal storm warnings service.

Systems of Electric Traction in the United Kingdom.—There are at the present moment only about 29 miles of tramway in this country worked by electricity, though there are no less than

Digitized by Google

four different systems. Five lines, having a total length of 15½ miles, are worked on the third-rail system; accumulator cars run over two lines 4¼ miles long; and the bare aerial conductor system is favoured by three lines, having a length of 7¼ miles; finally, there is but one example of the open-conduit system, viz., the two-mile line at Blackpool. The third-rail system comprises, therefore, about 50 per cent. of the total mileage.

Utilisation of Water-Power in Switzerland.—The Canton of Berne has granted a concession for the utilisation of the water-power of the River Aar at Wynau for electrical purposes. By means of a canal, 1,100 yards long, a fall of 12 feet and a flow of water of 22,000 gallons per second, developing 3,000 effective horse-power, can be obtained. The power thus obtained will soon be taken advantage of in the thickly populated industrial districts of Central Switzerland. It is, moreover, intended to work the proposed Valsthal-Langenthal Electric Railway. Should the power mentioned be found insufficient in course of time it can without difficulty be increased to 6,000 horse-power, as the whole of the water embraced in the concession has a fall of 28 feet.

Owens College, Manchester.—At least two Bishop Berkeley Fellowships (value £100 for one year and renewable for a second year) are offered for award in December next. Applications must be sent to the Registrar on or before December 1st. Evidence of ability to prosecute some special study or research must be presented. A fuller statement of particulars and conditions will be found in our advertisement columns. A limited number of Honorary Research Fellowship appointments will also be made in December next. Applications must be made on or before December 1st. There are no emoluments attached to these Fellowships, but Fellows have equal opportunities for research in scientific subjects to those enjoyed by the Bishop Berkeley Fellows.

The Electric Lighting of the City.—At Tuesday's meeting of the Commissioners of Sewers, the Engineer said he had a communication of the greatest importance to lay before the Court, but seeing that nearly all the members had left he did not think its contents should be read except before a full Court. As a matter of fact, it was an application by the City of London Electric Lighting Company praying for an extension of time for one year in the lighting of the City. He was sorry he had not had an opportunity of bringing the letter up before, but it only reached him on the previous day.—Mr. Smallman said the matter was of such importance that he would move that the communication be printed and circulated among the members immediately.—This was agreed to.

Underground Railway Projects.—In the ensuing Session of Parliament a Bill will be promoted to obtain power to construct an underground railway from Waterloo Station, passing under the Thames on the west side of Hungerford Bridge to a point near the Charing-cross Station of the District Railway. Thence the railway would proceed under Northumberland-avenue, Trafalgar-square, Haymarket, Piccadilly-circus, Regent-street, Regent-circus, and Portland-place to its termination at Baker-street Station.—The Hampstead, St. Pancras, and Charing-cross Railway has notified its intention of seeking powers next Session to construct an underground railway from Hampstead to Charing-cross, the line of route following as nearly as possible the main thoroughfares between Charing-cross and the north-western suburb.

The County Council and the Testing of Meters.—We printed on page 26 of our last issue a letter from a Mr. G. W. Hemming complaining of delay on the part of the London County Council in testing electric meters sent to them. Some further correspondence has taken place, from which it appears that, although some 35 Shallenberger meters were sent to the Council on the 23rd of September, it was not until the 9th of October that the Board of Trade notified to the County Council its approval of any type of meter, without which approval the County Council could not proceed to test. Some difficulty has also been experienced at the County Council's laboratory in Cranborne-street in regard "to testing for the alternate current," a difficulty, which, it is stated, "will take some little time to overcome." It is hoped that a few meters may be certified within a fortnight, but some few weeks more must elapse before the additional apparatus found necessary for testing will be ready for regular work.

The Protection of Telephones.—According to an engineering contemporary, it has been found necessary in America to protect the telephones by the three following devices:—Firstly, currents exceeding 450 volts are shunted to ground by an air cut-out, consisting of two carbon plates separated by a perforated sheet of mica, thin enough to allow the arc to jump through the orifice and set up a connection to earth. Secondly, a fuse which will be melted by a large current is introduced into the circuit. These fuses generally consist either of an easily fusible wire in a glass tube, ⅛in. in diameter, and 5in. long, or tinfoil between asbestos paper. Thirdly, a ball of wax, about ⅜in. in diameter, rests against the coils of an electro-magnet, and when it becomes softened by the gradual warming of the magnet coils it becomes flattened by the pressure of a spring bar pressing against it, and this motion in turn shunts the apparatus out of circuit.

French Electrical Installation Rules.—The French "Union" Fire Insurance Company has procured from MM. Bunel and Picou a full report as to the precautions which in their opinion should be taken in the use of electricity. The principal recommendations of the report are as follows:—The current density is not to exceed 2 amperes per sq. mm. (1,300 amperes per sq. in.) in wires of 10 sq. mm. (No. 9 B.W.G.) section and above, and 3 amperes in the case of smaller wires. Bare conductors are to be prohibited in buildings, and only allowed in exceptional cases in workshops. The protection of the conductors must be doubled, electrical and mechanical. The current leakage must not exceed one-thousandth of the total flow. The use of earth, or of gas or water pipes, or metallic girders, for return currents, is forbidden. The fuses must be double, and must melt with not more than a three-fold current. Resistance-coils must not be heated more than 100° C. Glow lamps must not be put on gas-fittings unless the gas is definitely cut off. Every place containing accumulators to be classified as dangerous, and to be subject to special precautions. Places where gas and electric fittings coexist to be classified as dangerous or very dangerous. The fire risk of gas lighting being represented by 4, the report concludes by estimating the risk as 3, when the electric lighting stands alone and the above regulations are strictly carried out; as 3 to 5, if there be any imperfection in the fittings; as 6, if gas and electricity be both used for lighting; and as 4, if the gas be used only for driving motors.

Brighton.—The Brighton Town Council, who are at present supplying part of Brighton with the electric light from works of their own, had before them yesterday a report of the Lighting Committee, recommending, as the result of certain negotiations, that the Brighton Electric Light Company be paid £7,000 for their goodwill, on condition that they relinquished their business within the Corporation lighting area on receiving a month's notice, and that they cease their supply in other parts of the municipal borough on receiving a year's notice, which, however, shall not terminate earlier than December 31st, 1893, the Company also undertaking not to apply to Parliament again for powers to supply the light in Brighton. The Company to retain their plant and take down their overhead wires.—The Company at starting proposed that the Corporation should take over the whole of its undertaking within the borough, including works and plant, at the price of £17,500. The Corporation refused. Negotiations, therefore, proceeded for the purchase of the goodwill alone, and for this the Company asked £13,000. This offer was subsequently reduced to £10,600, then to £9,850, then to £8,500, £7,500, and ultimately to £7,000. The price offered by the Committee was at first £6,000, but in the middle of the negotiations this was increased to £7,000, at which sum an agreement was at length arrived at. The purchase money is to be paid at once. The additional output thus to be acquired is estimated at 72,400 units per annum. According to the *Sussex News*, the outlay already incurred in connection with the Corporation Electricity Works has exceeded the estimate by £5,000.—After considering the subject in private yesterday (Thursday) the Council rejected the proposal.

Digitized by Google

Sydney.—Prof. Threlfall and Mr. E. C. Cracknell have presented their report on electric lighting to the City Council. For street lighting it is proposed in the principal streets to employ 431 2,000 c.p. arcs hung on poles 35 to 40 feet high, 90 yards apart. The mains for the arcs will be underground. The less important thoroughfares are to be lighted by 25 c.p. incandescents with overhead wires. For private lighting a 20,000 light plant is recommended. The total cost for the installation of the street lighting system is estimated at £105,696, and the total annual cost of maintenance at £15,833, or a little over £24 per annum for each arc, and £3. 12s. for each incandescent; the cost of installation of the private lighting plant is estimated at £60,737, and a reasonable profit is figured out on the basis of 8d. per B. T. U. (gas = 5s. 6d. per thousand). The present annual cost of the street lighting is £12,500. The City Council are now considering a Bill giving them powers to establish a system of electric lighting, to grant concessions for private lighting, and to borrow a sum not exceeding £250,000.

City and Guilds Technological Examinations, 1891.—At the recent examination the total number of worked papers was 7,416, as against 6,781 in 1890, showing an increase of 635, the corresponding increases in the two previous years being 175 and 440. This year, too, there is not only an increase in the number, but also in the proportion of candidates who have succeeded in satisfying the examiners, the number of passes being 4,099 as against 3,507 in 1890, and the percentage of passes 55·3 as against 51·8. Examinations were held this year in 53 as against 49 subjects in the previous year, and in 245 as against 219 different centres throughout the country. In the subject of "Mechanical Engineering" there has been a falling off in the number of candidates since 1888. It is thought that this continuous decrease in the numbers during the last four years is partly due to the character of the Syllabus of Examination, which, it is feared, is not as well adapted as it might be to the requirements of artisans engaged in this important branch of industry. The syllabus published in the new programme has been accordingly to some extent revised, and its further revision is under consideration. In "Telegraphy" the number of candidates has risen from 117 to 206. In "Electric Lighting," 392 candidates presented themselves this year as against 256 in 1890, and the number of successful candidates has increased from 173 to 262.

The Electrical Utilisation of Water Power in Sweden.—The utilisation of water power in Sweden through the medium of electricity is, says *Engineering*, a question which is forcing its way to the front. One of the waterfalls likely to be first dealt with is the Trollhättan; and a committee, consisting of five members, has just been appointed by those interested to thoroughly investigate the matter. A calculation has already been made with regard to the transmission of power from the waterfall to Gothenburg (about 40 miles distant). It is expected that some 7,000 H.P. would be required in Gothenburg, leaving out of consideration joineries and sawmills, which produce their own fuel. The cost of electric transmission is calculated at 70 kr. (£3 18s.) per horse-power per annum, irrespective of the cost of the waterfall itself, and the present prices for power in Gothenburg are put at 66 kr. (£3 13s. 6d.) for large concerns, 77 kr. (£4 5s. 6d.) for medium-sized, and as much as 200 kr. (£11 2s.) per horse-power per annum for the small industries. From this it appears that the large industrial establishments are not likely to derive any material benefit from the electric power, and if these are left out there only remain about 2,000 horse-power, for the sake of which it might hardly be worth while installing an electric power plant. If an electric light installation, however, could be connected with the power transmission, the affair would assume another aspect, and in all probability prove remunerative if the waterfall could be obtained free of charge or at a nominal cost.

The St. Pancras Vestry Central Station.—At the weekly meeting of the London County Council on Tuesday the Finance Committee reported that they had considered the application from the Vestry of St. Pancras for a loan of £60,000 for electric lighting works, repayable in 42 years. With regard to the period of years over which the loan should be spread, the Council was precluded from making advances to Vestries for works other than street improvements and bridges, for more than 30 years; and as the engines, boilers, dynamos, batteries, &c., could not be expected to last for above half that period, the Committee were of opinion that the usual course should be adopted, viz, to limit the period of repayment to the assumed life of the respective works, although they considered that the works being expensive and unremunerative at the outset, the repayment might be deferred for a period of two years. They recommended that the application of the Vestry should be granted to the extent of £56,300, on condition that the loan was taken up at once, interest being charged thereon at the rate of £3. 5s. per cent. per annum. Mr. Eccleston Gibb said that the policy indicated in the report would, if carried out, have the effect of destroying the work. If it were impossible for the Council to lend the money to the Vestry on the terms asked, it would be necessary to go to Parliament to borrow, and Friday was the last day on which notice could be given. Mr. Wetenhall pointed out that St. Pancras had taken the initiative in the matter of electric lighting, and that the demand for it in the parish was larger than could be supplied. Ultimately the paragraph was taken back.

The Ether.—The following letter, which appeared in the *Engineer* of October 30th, will probably be read by many with sympathetic interest:—

SIR: In the present day the ether has come to play an overwhelmingly important part in physical science. The whole fabric of the theory of light is based on it: without it radiant heat could, we are told, have no existence. Electricity and magnetism are manifestations of some ethereal action. Is it not about time that physicists enunciated some views concerning this ether which could be understood? Sir W. Thomson has written concerning it largely, and has built up a wonderful gyroscopic structure, with spinning tops within spheres, and called this the ether. Dr. Lodge tells us that the ether is a continuous elastic fluid, without structure or weight. The dynamo shears this fluid asunder, and the desire of the cut surfaces, so to speak, to unite, manifests itself in what we term electricity. It seems to be clear that Dr. Lodge and Sir William Thomson cannot both be right. Again, it has been definitely stated by a French physicist that it is impossible to explain all the phenomena of light, save on the assumption that there are at least six different ethers. An English professor of eminence said years ago that the whole theory of light was tottering to its fall, because of phenomena which no conceivable ether could account for. I ask, now, in all seriousness, if it is not time that some authoritative pronouncement should be made concerning this same ether. Is it, for example, a molecular elastic fluid of great density pervading all space, and of discrete structure, or is it a jelly-like homogeneous body? If it is absolutely imponderable, it must, I take it, be absolutely without inertia or momentum. But if it has neither inertia nor momentum, how can it transmit energy? Let us suppose that radiant heat travels at the same rate as light. When the sun sends us a foot-pound's worth of radiant heat energy it will be eight minutes on the road. What is it stored up in during those eight minutes? In the ether? It seems to me that on such points as these numbers of able men must think very clearly. Now I, and no doubt many other engineers, would like to have equally clear views, and we naturally turn to eminent physicists for light and leading. Which of them will help us?—A. T.—Westminster, October 26th.

Electricity in Mines.—The following extracts from a Paper read by Mr. Albion T. Snell, before the South Wales Institute of Engineers, may be of interest. At Newbridge Rhondda Colliery it was required to drive two pumps 700 yards apart off the same set of mains, each was to be completely independent of the other, and the electric lights must not be affected by their operation. The generator was over compounded to give a constant pressure near the centre of the system, with the result that both the pumps can be switched off without appreciably raising the voltage of the lamps. The dynamo, running at 800 revolutions, gives a pressure of 300 volts and 60 amperes Each of the motors gives 7 B.H.P., and runs at 800 revolutions per minute. The lamps are coupled, in series of three. The pumps are three throw rams, 4in. in diameter by 9in. stroke. An interesting plant, illustrating the conversion of water power into electrical energy and its utilisation for light and power, has been also designed by Mr. Snell. One thousand yards from the Greenside Lead Mines, near Ullswater, there is a 100 H.P. waterfall. A turbine, running at 1,000 revolutions per minute, is coupled by belt to a 100 E.H.P. 4-pole transmission dynamo, compound wound, to give 625 volts and about 900 amperes. The energy is transmitted by a bare wire 19/15 S.W.G. to the mine, and there lead-covered cables are used to convey the electricity to the various motors. These run a winding plant of 10 B.H.P., a pumping plant of 10 B.H.P., and another winding plant of 20 B.H.P. is under consideration. Electric light will be used at different points of the line, and other motors will soon be installed for various purposes.

ON THE DETERMINATION OF ELECTRIC CURRENT CURVES.

BY DR. O. FRÖLICH.

Electrical engineering has long since arrived at the stage at which it became desirable to ascertain the form of the curves determined by the relation between the current and the time in various cases. The first instances in which this necessity arose occurred in connection with telegraphing on long cables or circuits of large capacity: more recently the influence of self-induction and capacity on alternating current practice has come to the front.

The slowly moving curves such as were met with in cable telegraphy were directly recorded by well-known apparatus such as Sir William Thomson's syphon recorder and Siemens and Halske's soot writer; for the quickly moving curves such as are found with alternating currents, these instruments are too slow, and apparatus has had to be used with which we can measure the current at stated intervals and then set out the curve from the measurements so obtained. Although this method gives accurate results it does not supply the want felt by engineers when carrying out experiments: for this purpose some arrangement is required which will at once exhibit the curve as it is produced, so that any alteration made in the apparatus can be observed immediately on the curve, and the latter can be recorded in a simple and practical manner.

This problem is similar to that which occurs in registering sounds, and it is accordingly only natural that we should first investigate the methods which have been successfully applied in this case. The best known of these is that of Lissajous', which was also frequently adopted by von Helmholtz in his experiments on sound. After having worked for some time on these lines, and arrived at certain results, the method was abandoned, inasmuch as it gives not the actual curve but its development on a cylindrical sleeve, and because, consequently, the various portions are not set out with equal accuracy. In such experiments the bodies from which the curve is to be obtained must undergo a motion of the nature of such a vibration as occurs in a tuning-fork. For electrical curves a telephone, on the membrane of which a mirror was fixed excentrically (*i.e.*, between the centre and the circumference), was used with success, the current which was to be investigated being allowed to circulate in the coils.

When a telephone thus arranged was used in combination with a rotating mirror, such as is often used in physical experiments, and a powerful beam of light after reflection at the telephone and the revolving mirror allowed to fall on a screen, the required curve was at once obtained in a form readily observed. Since, however, this curve was not at rest, but moving over the screen, it was not possible to examine it with the necessary accuracy. In order to bring its oscillations to a fixed position on the screen *the two motions, that of the rotating mirror and that of the telephone membrane, must be combined in a definite manner.* If the apparatus was so arranged that one electric oscillation—*i.e.*, one movement backwards and forwards—of the membrane corresponded exactly with one revolution of the rotating mirror, and the latter contains only one reflecting surface, a part only of the curve, though *fixed in position*, was obtained, the beam at each passage over the screen tracing the same curve at the same spot, and the illuminated curve appearing stationary when the motion was rapid. In order to arrive at this result the movements of mirror and telephone must be performed in time with one another.

In order to obtain the whole of the curve, and of such a magnitude as would be convenient for photographing for instance, and also to get it repeated as often as possible, the rotating mirror was provided with a number of reflecting surfaces, and the proportion between the number of mirrors passing and the period of electric oscillation rigidly fixed. A series of rapidly succeeding illuminated curves was then obtained in the same place on the screen, and these could easily be observed, examined, and photographed.

This arrangement also possesses the great advantage that the process of production is *independent of the speed* of the mirror and the electric oscillation; the wave-length of the image remains constant. In this way, then, the effect of an alteration in the current period on an electric curve may easily be observed, and the process may readily be applied in the case of long-cable telegraphy, induction coils, alternators, &c.

As a source of light a powerful arc lamp was used, and in order to obtain a parallel beam of somewhat small section, the ordinary combination of lenses was adopted. Fig. 1 shows the optical arrangements. B, arc lamp; L l, lenses; o, screen with small aperture; s, telephone with mirror; R, revolving mirror; S, screen on which are thrown the images of the curves.

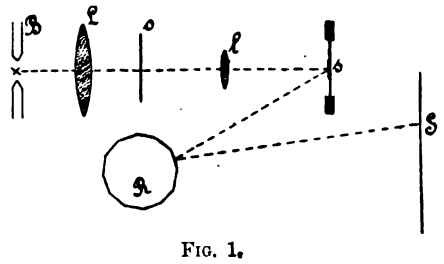

FIG. 1.

The revolving mirror was provided with 12 silvered reflectors, and a special device was adopted in order to bring these parallel to the vertical axis of rotation and at equal angles to each other. The mirror was fixed to a gear-wheel, driven off the spindle of a small alternating motor; for investigation with direct currents a commutator such as is used on small dynamos was fixed to the motor spindle.

The proportions were ordinarily so chosen that the wave-length on the screen came out at about 12cm., and the amplitude 6cm. In a darkened room an audience of 200 persons could then see the curve without leaving their places. When

FIG. 2.

photographs were to be taken, a camera with a plate was used instead of the screen.

The curves given by this apparatus do not necessarily correspond to the current in the telephone coils, but to the movements of the membrane actuated by it. In order that the former curve may coincide with that which we wish to investigate, a membrane must be obtained which shall reproduce as accurately as possible the current curve. This desideratum, however, also enters into the production of a good telephone, and consequently we cannot do better than use an ordinary telephone membrane.

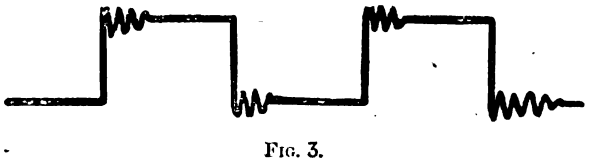

FIG. 3.

I found from my experiments and the theory that every membrane acts like a damped pendulum; the motion of the membrane taking place in accordance with its proper period of vibration and the damping force, as well as with the alterations in the current. We can determine the two former values for a given membrane by opening and closing, at regular intervals, a circuit passing through the telephone, an inductionless resistance, and a set of accumulators. The current-curve must in this case be that given in Fig. 2: the telephone, however, gives us that in Fig. 3. From a comparison of the two the two constants of the membrane, namely its period and the damping, can be ascertained. When these are known, any curve of the current flowing through the telephone can be deduced from that produced by our method by means of [redacted]raphic construction.

Digitized by Google

It is only in the case of sudden alterations in the current that any considerable difference between the current curve and the membrane curve arises. When the changes take place comparatively slowly, as in an ordinary sine curve, the ob-

Fig. 4.

served curve gives that of the current sufficiently exactly. Practically, then, the curve need only be corrected in the case of sudden current changes, when the effect of the period of the membrane becomes marked, and then a mean curve is drawn taking these vibrations into consideration (*see* Fig. 4). In most cases this is sufficient.

of the ordinary telephone membrane is here distinctly perceptible.

In obtaining Fig. 6 the membrane was replaced by a cardboard disc, to which was attached a small piece of thin sheet iron. The vibrations due to the proper period of the membrane

Digitized by Google

are here much stronger than with the ordinary membrane, and it is difficult to make out the real current curve. Since the card membrane gives a bad representation of the current curve, it must also when used in a telephone give a bad reproduction of speech. This was confirmed by a direct experiment.

Fig. 7 shows the charge and discharge of a condenser, the circuit being almost free from resistance.

Figs. 8 and 9 give the current curve at the beginning and the end of a small cable, current impulses being taken from a battery. The former shows clearly the charging and discharging of the cable; the latter is smaller, and is apparently free from indications of charge.

Figs. 10 and 11 show the current in the primary and secondary windings of a transformer without an iron core. The retarding influence of self-induction when the current changes makes itself felt.

The curves in Figs. 12 to 17 were obtained with a small Siemens alternator. In Figs. 12 and 13 a resistance almost without self-induction was placed in the external circuit. In Fig. 12 the armature producing the current consisted of wire only. In Fig. 13 an iron core was used in the armature.

It is obvious that these curves differ considerably from a sine curve. The rise and fall are different, and the use of iron produces secondary maxima and minima.

Figs. 14 and 15 show curves obtained on circuits of the same resistance, self-induction being provided in the former case by means of an electro-magnet, the latter being without such self-induction. The amplitude and mean current in the former case are clearly smaller.

Figs. 16 and 17 show the difference in phase in two external circuits in parallel, self-induction being put in in the one circuit only. The black band in the two curves is the shadow of a rod that was attached to the screen on which the images were produced in order to arrive at a fixed time mark. In one curve the mark falls by chance at the maximum of a wave, whilst in the other it is a quarter of a wave length to the right. I may here remark that the determination in this manner of the phase difference in alternating currents, wherever an iron core exists, gives results quite different from those to be expected from theoretical considerations.

From the foregoing examples it appears that this method is well fitted for obtaining reproductions of any desired current curves in a direct manner; and in particular it seems to call for some new explanation of the behaviour of alternating currents, in investigating which hitherto one has been compelled to be satisfied, even in experiments, with taking mean values for the electrical quantities. The above investigations were conducted at Messrs. Siemens and Halske's laboratory in Berlin (vide *Elektrotechn. Zeitschr.*, 1889, p. 345).

PRELIMINARY NOTE ON A METHOD FOR DETERMINING THE PERIODIC CURVES OF ALTERNATING CURRENTS.

BY DR. LOUIS DUNCAN, JOHNS HOPKINS UNIVERSITY.

The experimental methods heretofore used for the determination of current and electromotive force curves in alternating circuits present many difficulties, and are cumbersome and tiresome. Most of those now in use are based on the experiments of Joubert, who obtained the E.M.F. curve of a de Meritens dynamo by making instantaneous contacts between the dynamo circuit and measuring circuit at different points on the E.M.F. curve. This method was modified by Messrs. Wilkes, Hutchinson, and myself,* to give curves of primary and secondary E.M.F. and current in alternating circuits containing transformers, condensers, &c. Our method has been copied by Prof. Ryan and others, and the results which we obtained some years ago have been duplicated and extended. M. Blondlot has recently still further modified the method by using a galvanometer, through which a condenser charged to a potential representing different points on E.M.F. curves is discharged, the deflections being photographed. By using two contact, making arrangements or wipers, with two galvanometers, two curves were obtained at the same time.

The difficulties of most of these methods lie in the very considerable potentials used on the commutators—as much as 1,500 volts in some experiments—the fact that only one curve can be obtained for each commutator, with the possibility of error due to the contacts.

The following method is simpler and gives better results. To get the four curves of primary and secondary E.M.F. and current, four small dynamometers are made, and their stationary coils wound for primary current, primary E.M.F., secondary current and secondary E.M.F. respectively, their movable coils being connected in series in circuit with a few storage or other cells; this latter circuit having one end connected with a contact point on the dynamo shaft, the other end connected to a wiper touching the contact point at each revolution. The wiper is moveable through the arc of a circle (180deg. is sufficient unless the curves are to be photographed). These dynamometers may be cheaply and quickly made with wooden spools and a quartz fibre suspension, the current being carried by pieces of coiled tinsel or fine wire, as in a d'Arsonval galvanometer. Four of them may be easily made in a day.

In making the experiments, the deflections of the dynamometers are either observed or photographed. It is evident that if the instantaneous current in a moveable coil occurs when the current in the stationary coil is zero there will be no deflection; if the latter current is at its maximum, the deflection will be a maximum; while, for intermediate values, the deflection (I am considering small deflections, of course) will be proportional to the instantaneous value of the current in the stationary coil. By moving the wiper through 180deg. continuously, if we are photographing* we get all of our curves simultaneously, with no possibility of altered conditions changing their relative values. A galvanometer in circuit with the moveable coils allows an absolute scale to be applied to the curves after the dynamometers have been once calibrated, and eliminates any error caused by the wiper. We are thus able to obtain any number of curves simultaneously with only one commutator, with only a few volts on this commutator, and with no possibility of errors due to the contacts.

* *Electrical World*, March, &c., 1888.

* If the curves are to be photographed the wiper should be slowly reversed.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

FRIDAY, November 20th. (To-night.)

PHYSICAL SOCIETY.

5 p.m. Paper to be read:—"A New Theory concerning the Constitution of Matter." By Dr. C. V. Barton.

TUESDAY, November 24th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Papers to be discussed:—(1.) "Portland Cement, its Manufacture, Use and Testing." By H. K. Bamber. (2.) "The Inspection of Portland Cement for Public Works." By A. E. Carey, M. Inst. C.E. (3.) "The Influence of Sea-Water upon Portland Cement, Mortar, and Concrete." By William Smith, M. Inst. C.E.

WEDNESDAY, November 25th.

SOCIETY OF ARTS.

8 p.m. Ordinary meeting. Paper to be read:—"Measurement of Lenses." By Prof. Silvanus P. Thompson, D.Sc., F.R.S.

THURSDAY, November 26th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting, continuation of Discussion on the following Paper:—"Description of the Standard Volt and Ampere Meter used at the Ferry Works, Thames Ditton." By Capt. H. R. Sankey and F. V. Andersen.

FRIDAY, November 27th.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. Paper to be read:—"Modern Railway Carriages." By Walter Clemence, Stud. Inst. C.E.

JUNIOR ENGINEERING SOCIETY.

8 p.m. Presidential Address by Sir E. J. Reed, F.R.S., M.P.

ELECTRIC HARMONIC SOCIETY.

8 p.m. Ladies' Night, Concert at St. James's Hall Restaurant.

ELECTRIC LIGHT CABLES.

The method of specifying the insulation of electric light cables for house-wiring seems to be in a rather unsatisfactory condition. There are three elements to be considered: insulation resistance, the nature of the insulating material, and its thickness. The first of these appears to be of the greatest importance in the opinion of many persons, among whom may be included most cable makers. The hundreds or thousands of megohms per mile are sure to be given in their price lists, whether the nature of the insulation is described or not. For submarine cables the number of megohms per mile is no doubt important; every megohm has its duty to perform; and in street work, where the conduits may be flooded, the insulation indicated by this description may sometimes be put to trial. But for house work the uselessness of these megohms is proved by the fact that enquiries are rarely if ever made as to the conditions under which their value was arrived at. A contractor desirous of doing good work will avoid any cable described as offering less than 300 megohms per mile; but he very rarely thinks of making enquiries about the duration of immersion, the volts under which the test was made, how long they were applied, or, indeed, whether an electrification or bridge method was used. The temperature of the test is occasionally given in the price list, a detail which is of as much importance as whether salt water or fresh was used. When only three or four megohms per house are required, a contractor will not make a fuss about hundreds per mile; but, at present, these meaningless megohms are his chief guide to the quality. The Chelsea Electric Supply Company indeed demand 600 megohms per mile, and say nothing whatever about megohms per house. The mere fact that the ultimate insulation of the circuit in an ordinary house is about the same as that of several hundred miles of the cable used shows the unsatisfactory state of the present custom. Before the art of wiring was understood, an

Digitized by Google

important part of the work consisted in making joints; and these were so often a source of trouble, and the weakest part of the circuit, that it was common, in making an inspection, to lay bare one or two for examination. But now that joints are confined to distribution boards, and are otherwise either absolutely forbidden, or are reduced to a few large and easily-looked-after instances, the leakage is to be traced almost entirely to fittings; but we may look in vain in the price lists for a guarantee of so many megohms per switch or lampholder. The excellent china fittings that are made to-day, with no screws coming through from the back, are an example of the improvements which are accepted readily enough, because common sense shows that a well-considered attempt has been made to combat with leakage. A careful contractor uses them in the hope that his insulation will be better, but he never thinks of them as being of a definite insulation resistance.

The second element, that of quality, has been attended to of late, partly because it was found to be impossible to get the insulation demanded by the supply companies on a house wired for 50 lights, with wire of inferior quality. We do not remember ever having seen a price-list offering a resistance less than 150 megohms per mile; the insulation of the lower classes is discreetly passed by in silence. Another reason, however, is the persistent effort of Mr. Musgrave Heaphy to exact the best qualities only; and while much annoyance was felt at one time when vulcanized rubber was demanded, a result has been that almost all makers have put down vulcanising plant, and there is no difficulty in getting cables so insulated. But a consulting engineer does not like to specify a particular kind of insulating material. Another kind may turn up, and he finds himself unable to say why it should be excluded, while to mention the names of particular makers is invidious. If he gives several names, and classes Brown's AA, Jones's G, and Robinson's X, picking those which are of similar or comparable material and of corresponding insulation resistances, the contractor, being relieved of responsibility, will compare prices, and will take that which he can buy best. But comparisons of price-lists are very bewildering. One maker sells 7/16's for £75 per mile and puts it at 2,000 megohms, while another charges £79 for the same size of conductor with 300 megohms. The general public are beginning to have some notions about volts and amperes; but this comparison would convey nothing to the average man except a confused idea that one manufacturer sold with his cable something called a megohm at 9d. apiece, while another charged about 5s. 3d. He would, of course, be told by an electrician that this conclusion was quite wrong, and, by way of clearing the matter up, the latter would perhaps explain that the expression megohm-miles, not megohms per mile, would be the more correct. Unsatisfactory as this mode of description of the quality of cables may be, it is very difficult to find any better. It will not do to specify the insulating material, as was done in the original draft of the overhead wire regulations of the Board of Trade. If, as in that case, india-rubber be specified, vulcanised bitumen will be offered by one maker and a mysterious compound called okonite will be produced by another; and these cannot be rejected as inferior in any way to the older and better known material. Some new mixture may be introduced any day; and it is surprising that coal tar has not yielded some "waste product" of suitable electrical and mechanical properties. The worst quality of insulated wire may be avoided by a suitable specification, but the best cannot be ensured without insisting on these thousands of megohms, which are not really necessary.

It will not do to merely specify the thickness of the insulating material and its composition, for after all some insulation resistance is wanted, even though it need not amount to many hundreds of megohms per mile. Most manufacturers maintain a proportion between the diameter of the conductor and the external diameter of the cable. A certain thickness of insulating material is necessary to resist mechanical abrasion. A wire covered with cotton and saturated with shellac serves for a dynamo armature; and although careful makers cover the core with mica before winding, there are thousands of dynamos in use with only a layer of tape between the wire and the iron. But this sort of insulation, though electrically efficient, would never do for wiring a building. In cases where high volts are employed the thickness of the insulating material does more than merely increase the actual insulation resistance; and the thickness specified in the overhead wire regulations was, we believe, intended as a precaution against sparking through any accidental cracks in the covering. Even if the large external diameter is really necessary, it need not in this case be built up entirely of the best insulating material.

The prices and qualities of electric light cable do not differ more than those of boots. Tenders to a careful specification for boots run, so we are informed, very close together; but the price is somewhere about 5s. 6d. a pair. We asked the manager of a large West End business if the first-class quality of boots could possibly be ensured by specification, and he admitted that he could not see how it could be done. But nobody says that bootmaking is in its infancy because the price varies from 5s. 6d. to £3 per pair. The safest way to get a first-rate electric light cable or a good pair of boots is to go to a first-rate maker. The smaller men may say that this is hard on them; and it is these smaller men who have their opportunity when asked to tender. It is all the more important, therefore, that it should be possible to describe the really essential qualities of a cable properly in a specification.

A case occurred recently in Cologne, not indeed of house-wiring, but of mains laid in the streets, where the difference between the tested insulation resistance of the cable and its resistance when laid was indeed fully realised by the authorities. The guaranteed insulation of the cables was fixed at 700 megohms per kilometre before laying, but only 7 megohms per kilometre were demanded after laying. The actual insulation of the completed work turned out to be 1,600 megohms per kilometre, measured with low volts and a mirror galvanometer. The cable, which was of Berthoud-Borel make, stood a subsequent test of 5,000 volts. We were sorry to observe that in the course of a recent trial some cable which was badly cracked and unfit for outdoor work was said by more than one witness to be adapted for house-wiring. The difference in price between good and bad cable per house is quite insignificant compared with the variations between one tender and another. A contractor may, and generally does, find some cable maker who suits him, and he knows by experience that a certain quality of cable is satisfactory, and does not trouble himself about its description when he is not working to a specification. Some people think that there is a vast amount of good india-rubber and other material buried away in casing which is practically useless, and that only in the remote contingency of the bursting of a water-pipe will its insulating property be called into play, and that this contingency may be provided against by a cut-out. But it has been proved over and over again that inferior insulation in the presence of damp will gradually deteriorate, and may ultimately char any neighbouring wood, so it seems advisable to stick to the hundreds of megohms; but it would be well to know rather more clearly than at present what each maker means by this description of his goods.

A FORGOTTEN TELEGRAPH PIONEER.

MR. JACOB BRETT.

At the ordinary general meeting of the Institution of Electrical Engineers on Thursday evening last week, the usual preliminary business was agreeably diversified. The President announced that the Council had elected Mr. Jacob Brett an honorary member of the Institution, in recognition of his valuable services in connection with the introduction of submarine telegraphy. He also announced two very interesting donations, viz., an excellent portrait in oils of Mr. Jacob Brett, painted and presented by Miss Alice Bolton, of 49, Blomfield-road, Maida Vale; and seven volumes of manuscript letters and manuscripts formerly belonging to the late Sir William Fothergill Cooke, relating to the introduction into England of the electric telegraph by himself and his partner, the late Sir Charles Wheatstone, presented by Mr. Latimer Clark.

Mr. LATIMER CLARK, in acknowledging the vote of thanks to himself, and in seconding a similar vote to Miss Bolton, said: I have great pleasure in seconding this motion, but before referring further to the subject I feel bound to return my thanks for the kind way in which you have accepted from me the letters, documents, and papers of the late Sir William Fothergill Cooke, which I have had the honour to present to the Institution. Anyone who looks into these letters will find their perusal very interesting, and I can vouch for the fact that they are historically extremely valuable, because they relate to the history of the introduction of the electric telegraph into this country at a date so early that it is not possible that anything earlier can be discovered. We owe it to the business aptitude and energy of Sir William Cooke, assisted by his partner, Wheatstone, that the electric telegraph was introduced on the railways in this country at a very early date and before it was taken up by other countries; so that Great Britain will for all time to come claim the honour of having first introduced the electric telegraph into practical use, as it can also claim the first invention of electric telegraphy through the celebrated letter of "C.M." in "The Scot's Magazine" of 1753.

Although I knew Sir William Cooke extremely well and for a great number of years, it was a long time before I could induce him to entrust to me the valuable papers he had in his possession. For many years I used, on every opportunity, to urge on him that they should be deposited in some public institution, and it was only some ten years ago that he at last consented to place them in my hands, as part of a large collection of works which I had been accumulating, and which I assured him would sooner or later find their way to some public library. When I did obtain possession of them, a great many were found missing, in spite of every search he could make. They now comprise seven volumes, containing all kinds of documents of a legal or business nature, and a great many private letters. Perhaps the most interesting part of the collection is a series of private letters to his mother and his brother, detailing the inception and early development of his ideas. He was most affectionately attached to his mother, and his letters to her abound in expressions of filial love which are quite touching. They were written in the old days of high postage rates, and, as was customary in those days, they were crossed and recrossed in such a way that it is difficult to read them, and would be still more difficult to find space for an additional 20 words in any of them.

Our honorary solicitor, Mr. George Bristowe, has very considerately made a copy of all those portions which relate to the electric telegraph, and this will be found in a separate volume. He has done this not only with a view to their more easy perusal, but he was impressed with their historic value, and he kindly undertook this duty with a view to their safe preservation from fire or other accident, deeming it unsafe that only one copy should be in existence. I will venture to read an extract from the first letter to his mother, dated April 5, 1836, because it is always interesting to trace the first movement in a path from which such mighty results are afterwards destined to emanate.

"Heidelberg, April 5, 1836.

"MY DEAREST MOTHER: You must know that for some weeks past I have been deeply engaged in the construction of an instrument which I believe may prove of sufficient importance, should I succeed in bringing it to practical perfection, to merit a visit to London. Determined to satisfy myself on the working of the machinery before I went any further, I prepared to make a model, and being unable to obtain the requisites at Heidelberg, I sought them at Frankfort. Whilst completing the model of my original plan, others on entirely fresh systems suggested themselves, and I have at length succeeded in combining the utile of each; but the mechanism requires a more delicate hand than mine to execute, or rather instruments which I do not possess. These I can readily have made for me in London, and, by the aid of a lathe, I shall be able to adapt the several parts, which I shall have made by different mechanicians for secrecy sake. Should I succeed it may be the means of putting some hundred pounds in my pocket. As it is a subject on which I was profoundly ignorant till my attention was casually attracted to it the other day, I do not know what others may have done in the same way; this can best be learned in London. You see I am very mysterious at present, and think it very prudent to continue so; nevertheless to you, dearest mother, if it were your wish, my plan and instrument should be explained now, though I think without better drawings than I could make you would scarcely comprehend me. As I do not wish my motives for revisiting London to be generally known, you had better, in mentioning it to any friends at Berne, state that private business requires my presence, and allow them to ascribe to modelling, or what they please, the sudden change of my plans."

This is a sample of the correspondence which goes on for a great many years. But besides these the collection comprises autograph letters from several very eminent persons, and many papers connected with the celebrated arbitration between himself and Sir Charles Wheatstone, and with the introduction of the telegraph and the formation of the Electric Telegraph Company, which was the first public company established for the purpose of telegraphic communication, and which opened its doors to the public on January 1, 1848, at which time about 1,500 miles of telegraph were in existence.

Life is proverbially uncertain, and I have therefore had very great pleasure in confiding these papers and documents to the care of the Institution of Electrical Engineers, and I thank you sincerely for the kind way in which you have accepted them.

I have now the pleasure of seconding the vote of thanks which has been proposed to Miss Alice Bolton, for her presentation to this Institution of the very artistic and excellent portrait of Mr. Jacob Brett which we see before us. Its artistic merits are very obvious to us all, and I can testify to its being an excellent likeness, as I have had the pleasure and privilege of knowing Mr. Brett for a great many years. It represents him not so much as he is to-day, but rather as he was some four or five years since, when the portrait was originally painted. Mr. Jacob Brett is now 83 years of age, and I grieve to say he lies on a sick bed through an accident which occurred to him some time ago in getting out of a vehicle; one of his legs was injured, and as the wound has reached the surface of the bone it is extremely difficult to heal. It is a great pleasure to me to know that Mr. Jacob Brett has been elected one of the very few honorary members of this Institution; for I feel that in conferring honour on Mr. Brett we have, perhaps unwittingly, conferred an honour upon ourselves.

I do not think it probable that many of those whom I see present with us this evening can be fully aware of the very important part which Mr. Jacob Brett and his brother, Mr. John Watkins Brett, have played in connection with the history of the introduction of the electric telegraph, and especially the Submarine Electric Telegraph, into the country and into the world. That connection dates back to a past generation, and is much deeper and more important than the world generally is aware of. His brother (Mr. J. W. Brett) and Mr. Brett were close friends and partners, and worked together in all their undertakings. His brother had a considerable fortune, which he was always ready to lavish on the advancement of submarine telegraphy. They commenced their public labours in 1845, and it is through their energy and devotion to the subject that we, as Englishmen, can claim for ourselves the distinction of having been the pioneers in the introduction of submarine telegraphy, as we can equally claim to have been the first nation to invent the electric telegraph and the first nation to

Digitized by Google

introduce it into practical working. In order to be able to appreciate the early date at which they began their labours I would remind you that in 1837 Cooke and Wheatstone exhibited the private working of their telegraph from Euston to Camden Town; and the public then, for the first time, became aware of the possibility of the introduction of the electric telegraph as a factor in daily life. During the ensuing years, Sir W. Cooke, by his great business energy, succeeded in establishing telegraphic lines on many of our railways, as, for example, the Norwich and Yarmouth line, the Dalkey atmospheric line, the Northampton and Peterborough, the South Eastern, the Great Western, and others. But on January 1, 1845, an event occurred which startled the public mind, and contributed most powerfully to the advancement of the electric telegraph. On this date occurred the notorious case of the murder of a woman at Slough, by the Quaker, John Tawell, and his arrest was effected by the telegraph. After he had left by train for Paddington, a description of the murderer was forwarded by telegraph, and on his arrival he was seen to enter an omnibus. A detective mounted on the roof, and after watching him through several streets in the city, followed him into a small eating-house in an obscure and narrow alley, and seated himself opposite to him. Having satisfied himself by observation that he was in the presence of the right man, he suddenly accosted him with the question, "Haven't you just come from Slough?" Tawell's astonishment and his haggard looks at once betrayed his guilt, and he was eventually condemned and hanged for the crime. This episode occurred in 1845, and made a great impression on the public mind, and I have no doubt had its influence on the action of the two brothers Brett; for, on June 16th of that year, they registered "The General Oceanic Telegraph Company." I shall have to refer later on to this Company, but for the moment I only call attention to its date and to the fact that "The Electric Telegraph Company," the well-known pioneer telegraph company of Great Britain, was not registered until September 2nd in the same year.

On July 23, 1845, the two brothers laid before Sir Robert Peel and the Government their plans for uniting Dublin Castle with Downing-street, and also for a general system of oceanic and subterranean electric telegraphs, to include the United Kingdom and the Colonies, together with the establisnment of a system of postal telegraphs throughout Great Britain. That letter was printed in type by an electrical type machine patented by the Bretts, which was exhibited at 29, Parliament-street, and I well remember seeing it at that time. Copies of the letter were extensively distributed, and I believe that the instruments themselves are still in the possession of Mr. Jacob Brett. In the following year, 1846, they applied to the French Government for a concession for a cable to be laid at their own expense from England to France; and in 1847, this concession was granted to Messrs. Brett by His Majesty Louis Philippe, and in 1849 was further confirmed by Louis Napoleon, the President of the French Republic. They also applied in this year for a Belgian concession, which was granted to them in 1852.

In 1850 they laid down their first submarine line, the well-known single wire of gutta-percha, which was successfully completed on August 28th, just in time to save their concession. That wire, as we well know, was so slight that it failed almost immediately; but it was followed in 1851 by a permanent cable of a very different character, which, subject to repairs, was working in portions for 20 years or more, in fact no record exists of the date of renewal of the last remaining portions of it. This cable contained four conductors, and was armoured with stout iron wires in the usual manner; in fact, it formed the type for all future submarine cables. The success of this line enabled them to form in 1852, "The Submarine Telegraph Company," Mr. J. W. Brett himself being one of the Directors, which proved one of the most prosperous and successful of cable companies, and has only recently passed into the hands of the British Government.

In 1853 they laid the first Belgian line, and formed "The Mediterranean Electric Telegraph Company," followed by cables to Corsica, Sardinia, Algiers and many other places, while they were incessantly active in pushing forward their great scheme for a line of cables across the Mediterranean to Egypt, the Red Sea, India and Australia. Mr. J. W. Brett was also a Director of "The British and Irish Magnetic Telegraph Company," which in combination with others formed so powerful a rival to the old Electric Telegraph Company.

Now it must ever be a source of surprise that with such records as these the name of Brett should have been omitted or forgotten in 1866, when the somewhat lavish distribution of honours and titles was made in consideration of the splendid success of the Atlantic undertaking; and that surprise will not be diminished when I proceed to show you, that Mr. J. W. Brett was himself the originator, and one of the earliest and strongest supporters of that project.

I have said that on the 16th June, 1845, Mr. Jacob Brett had registered at the Joint Stock Companies' office "The General Oceanic Telegraph Company," the first telegraphic undertaking ever registered. I have seen the original certificate and receipt. But what is more curious is that even at that early date, the application goes on to say: "Object specified:—To form a connecting mode of communication by telegraphic means from the British Islands and across the Atlantic Ocean to Nova Scotia and the Canadas, the Colonies, and Continental Kingdoms." So that we are met by the extraordinary fact that the first telegraphic company ever registered in this country was formed, not with the object of erecting telegraphs on land, but for the purpose of laying a submarine cable across the Atlantic Ocean, and this at a period when the world at large had not even heard of submarine telegraphy. Later on in 1855 we find Mr. J. W. Brett associated with Peter Cooper, Cyrus Field, Dudley Field, Prof. Morse, and other prominent names, in founding the New York, Newfoundland and London Telegraph Company, and I have seen the receipt for the £3,000 which he contributed in 1856 as his share to the common fund. In October, 1856, we find the Memorandum of Association of "The Atlantic Telegraph Company," with a capital of £300,000, in 300 shares of £1,000 each; and again we find Mr. J. W. Brett's name at the head of the list with a subscription of £25,000, followed by the subscription of a like sum by Cyrus W. Field; and subsequently we find his name at the head of the list of Directors of the Atlantic Telegraph Company, which was at first unsuccessful.

It is most difficult to understand how such splendid services in the cause of Atlantic telegraphy could have gone unrequited and unnoticed. One can only conjecture that he must have impoverished his fortune by his too great liberality in his efforts to advance the cause of submarine telegraphy; so that when the final victory was won, and the hour of triumph and reward came, he was unable to take his place in front, and was left aside unnoticed and forgotten.

I feel very much gratified that this Institution should possess a portrait of the only survivor of the two brothers whose names will go down to posterity as those of the fathers of submarine telegraphy, and I have therefore the greatest pleasure in seconding the vote of thanks to Miss Alice Bolton. We also owe a debt of gratitude to her and her mother for the affectionate care with which they have assisted Mr. Brett during many long years of public neglect. As for Mr. Brett himself, I regret to say that he is in extremely straitened circumstances. He has for many years subsisted entirely on a pension of £100 a year, which was granted to him from the Civil Service fund, and he has no other means of subsistence. It will ever be regarded as a matter of wonder to future generations that the rulers and merchant princes of the Victorian era, who have derived such splendid benefits from submarine telegraphy, should have permitted two of the noblest of the pioneers of electrical science to thus pass away unnoticed and almost unknown.

Mr. Brett is, however, fortunately a man of happy and cheerful disposition, and feels amply repaid by the knowledge that the subject to which he devoted his early life has now become of almost infinite importance to mankind; that by day and night myriads of signals are ceaselessly flashing through every ocean, and bearing their priceless messages of love or of commerce, of peace or of war. It is a pleasure to feel that when he shall be called away to his last rest, he will be sustained by the proud consciousness that he has been enabled to confer greater benefits on his country and on the world than any other man now living.

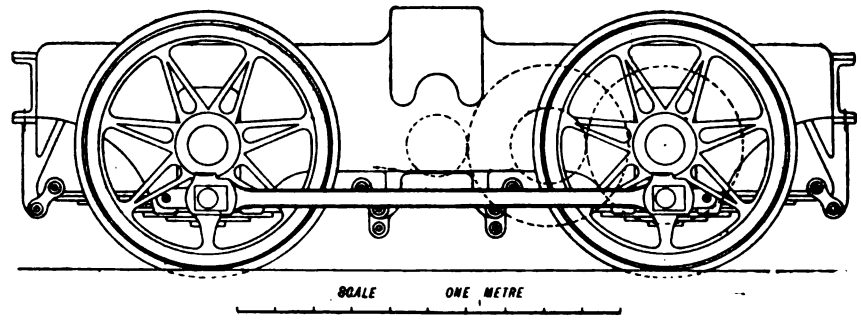
THE HAGUE AND SCHEVENINGEN ELECTRIC TRAMWAY.

Not contenting themselves with the natural facilities for traffic afforded by level roads and numerous canals, and a good railway service, the Dutch are well to the front in their very extensive use of tramways. The tram service in the larger towns is excellent, the fares are very moderate when compared with general prices and the limited buying power of Dutch money. An extensive use is made of steam tramways, which are wisely kept for inter-urban traffic; and, though running on the same lines and in connection with the horse trams, do not pass through the busy streets. The steam tram line from Haarlem to the Hague, passing by Leyden, runs in direct competition with the railway, canal, and road, but does an excellent business, stopping to pick up or set down passengers at or between the villages, and carrying goods as well as two or three cars of passengers. The nature of this traffic is well worth the attention of those who wish to introduce electric tram lines in this country.

During a recent visit to the Hague, which is well served by both horse and steam trams, we noticed some large and substantially-built double bogie cars, the wheels being coupled, but destitute of any visible means of propulsion. So little fuss was made about them that for a day or two we thought they were driven by compressed air; but on closer inspection it was evident from the starting gear that they were provided with accumulators and motors, though both of these were invisible. Finding that no branch of the line went near the electric light station (*The Electrician*, Vol. XXVII., p. 577), and experiencing some difficulty in expressing in the vernacular a wish to visit the charging station, we mounted a car and kept a look-out for it. The route lay to Scheveningen, the fashionable watering-place, about two miles distant. To the exorbitant hotel charges at Scheveningen is due the facilities for traffic from the Hague. A horse tram line runs along one side of the beautiful avenue connecting the two places, a steam tram line in connection with the State railways runs by a rather more circuitous route, and between the two, among the sandhills, and with gradients of 1 in 20, and curves of 14 metres radius, a remarkably smooth running line is laid for the electric tram. In the town, a moderate pace is allowed, but when clear of the suburbs a speed of 20 kilometres an hour is maintained, and an occasional spurt at 30 kilometres when the road is clear and the gradient favourable.



Elevation of Bogie.

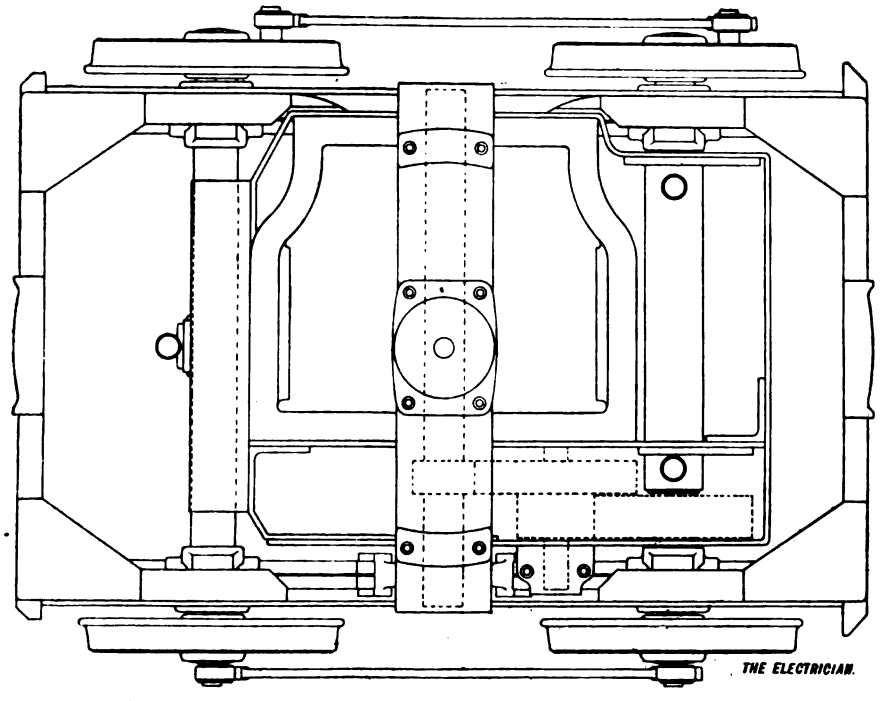


FIG. 1.--Plan of Bogie, showing Inner Frame and Outline of Motor.

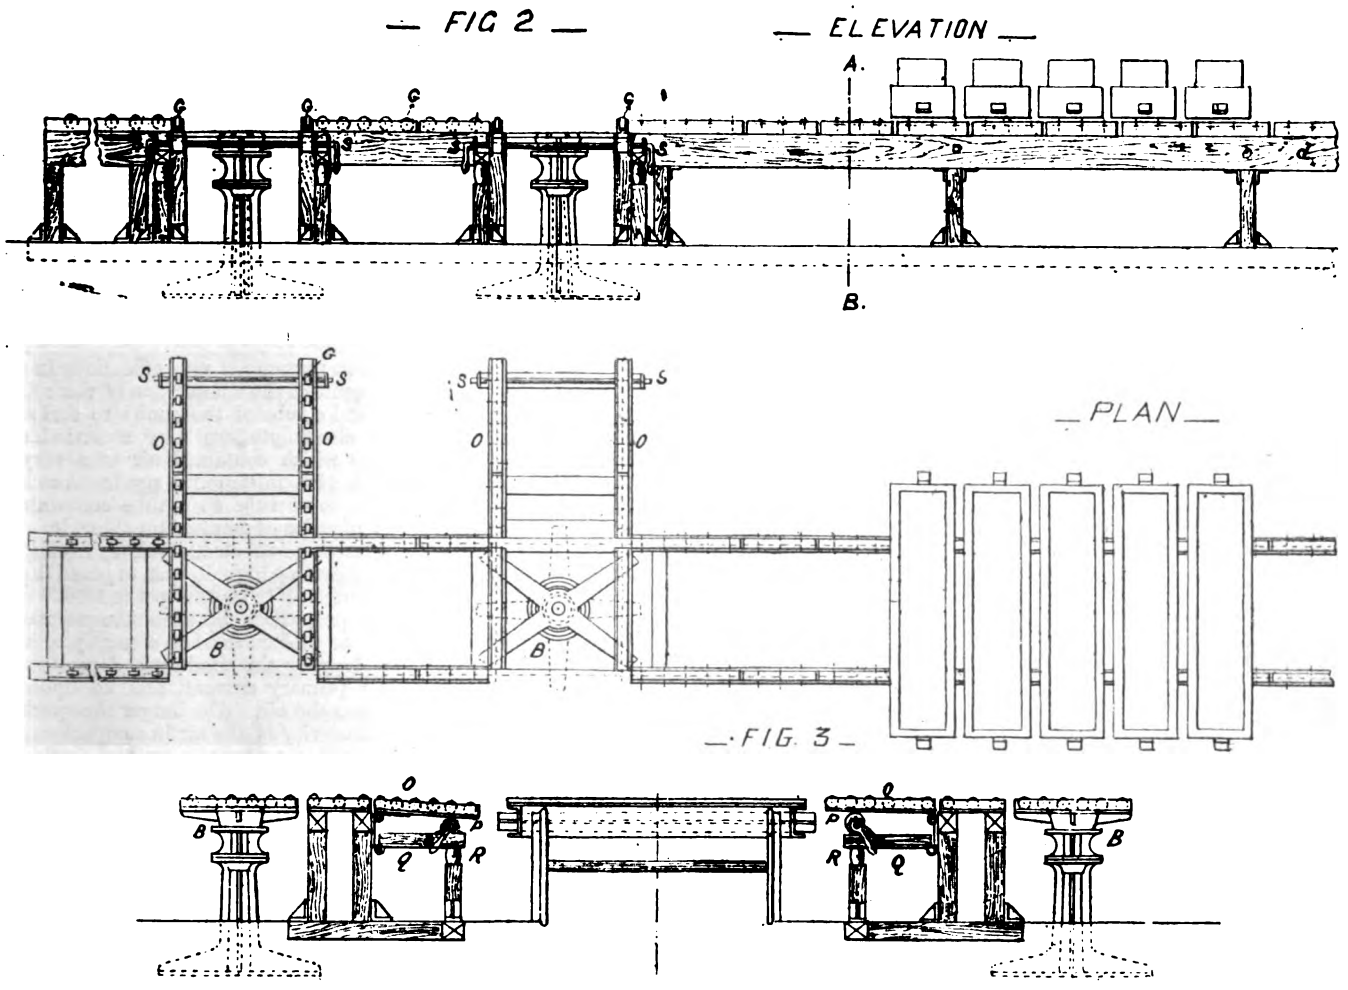
Among the dunes behind the Scheveningen Kurhaus a large station has been erected, consisting of an engine-room, charging shed, engineers' workshop driven by a motor, and a battery room, besides offices and dwelling-house. The workshop motor is worked from a battery which is also used for running 10 arc lamps. Three Silvertown dynamos, driven from countershafting, are run from two condensing steam engines, each indicating 210 H.P. Condensing water is supplied through a syphon from the canal 1,200 metres distant. A "Swiss" cross-bar plug board is provided, by which any dynamo can be connected to any charging circuit. An output of 60 amperes at 500 volts can be generated, the usual charging current on each circuit is 19 amperes at 450 volts, and this is controlled by a number of ammeters and hand resistance-regulators attached to the switchboard. The use of points for directing the cars into the charging shed, repairing shop, or the car shed, is avoided by a rolling transfer bridge; and a bridge in the repairing shop, provided with screwjacks,

Digitized by Google

and running over a long pit, enables the cars to be easily removed from the bogies.

The plant, as arranged by the makers, gave a good deal of trouble. Chain gear was used on the motors, and this was both noisy and subject to wear. When the management of the line was undertaken by Herr P. van Vloten, he designed the excellent system of changing and charging the batteries, and entirely re-arranged the motor. It was necessary to use the old motors and the outer bogies, but the gear and inner bogie were entirely reconstructed. Fig. 1 shows an elevation, and a plan of the present arrangement. An intermediate gear is used, and this, together with the driving wheel, is of cast steel. The pinion on the motor is of a pattern which has been re-invented several times. It consists of a number of discs of sheet steel separated by leather, the whole mounted on a hexagonal shaft and firmly screwed up. No signs of grooving were visible on the intermediate wheel. A pinion was shown us which had run some 6,000 kilometres; it was considerably worn, but by no means worn out. A new one can be refitted in a few minutes at no great cost. The gear is a very close fit for the inner bogie, owing to the reconstruction; a clearance of only two millimetres being possible at one point. The weight of the car is taken by the centre of the outer bogie, and is transmitted to the axles by three rubber springs, as shown in plan. The tractive force is transmitted from the motor to the inner frame by the bearings, and from this by short links to the outer bogie. These links allow of some vertical play between the two frames. The bearings of the axles have a vertical play in the outer bogie, as is shown in elevation.

The most remarkable feature at the station is the method of handling the accumulators for charging. A good deal of ground space is occupied, it is true; but such a station would generally be built outside a town, as in the present case. Two lines run the whole length of the shed, and examining pits are provided between the rails. On each side of the lines are benches or tables, 26 metres long, and on these the accumulators are charged in series. A car, containing batteries which require charging, is run to the end of the shed, and doors at the sides of the body are opened. These give access to the accumulators, which are arranged under the seats in eight sets, each weighing 500 kilogrammes. Each set is contained in a case, which is provided with contact strips, automatically making connection when run into place in the car. When a set of batteries is to be withdrawn, the car is placed so that a hinged bracket O (Figs. 2 and 3) is presented for their reception. The batteries are run out on to this bracket, which is provided with rollers G. When the battery is pulled on to the bracket, an eccentric P below the shelf is turned by a lever S, and thus the bracket is raised on its hinge, and the battery is run on further to a turn-table B. The eccentric is mounted on a lower hinged frame Q. A rubber buffer R is arranged underneath, to prevent any jar. A quarter turn being given, the set of batteries is run forward on to the charging bench *d*, rollers being provided throughout its length. The details for ensuring the insulation of the batteries and their electrical contacts with the charging current are very ingenious, and no mistake can be made in the connections. The eight sets of batteries can be run out simultaneously on to eight brackets and turn-tables, those already on the bench are pushed forward from time to time to make room, the charging going on all the time, all the sets being in series. The batteries can be removed from the car in about two minutes. The empty car is then run back towards the door of the charging shed, and at the other end of the charging bench a similar arrangement of turn-tables and hinged brackets is provided. Matters are so arranged that by the time a set of batteries has travelled the whole length of the bench it is fully charged. Two minutes suffices for running them into the cars, and five minutes after entering the



FIGS. 2 and 3. – Details of Charging Bench, Brackets and Turn-tables for Handling Accumulators.

Digitized by Google

shed a car can be run out again with a fresh set of accumulators.

Each car contains 4,000 kilogrammes of Julien accumulators. The plates are very thin, and are very close together. Thin ebonite boxes are used. The line as reconstructed had been running for some four or five months on the occasion of our visit without any perceptible deterioration of the batteries; but some changes were in contemplation, and it is proposed to manufacture a battery for the purpose on the premises.

The line outside the Hague is excellently laid on transverse sleepers; the motion is perfectly smooth and noiseless. The starting and change of speed is controlled by a resistance switch, combined with a commutator. A mechanical locking device is arranged, so that the commutator cannot be moved until the resistance switch, after putting in all the resistance, has cut off the current. The commutator enables the accumulators to be placed all in series for high speed, or in two sets in parallel for slow speed. Carbon brushes are used. Six cars were running last season, each being capable of seating 68 passengers. The length over all of the car is 10 metres. They were built by Beynes, of Haarlem, and weigh 16,000 kilos. A run of 70 kilometres—that is, seven double journeys—is made with one charge. The service is used only during the Scheveningen season, and the plant for charging and general accommodation is sufficient for a considerable increase of traffic. The cost of the service could not, therefore, be compared with other systems, but the engineering details are none the less interesting; and as the cars are run by the Haagsche Tramweg Maatschappij they will be able to compare their cost with the other portions of their service, and it is probable that some publication of the figures may be made before long.

ON THE DISCHARGE OF ELECTRICITY THROUGH EXHAUSTED TUBES WITHOUT ELECTRODES.*

BY J. J. THOMSON, M.A., F.R.S.

(Continued from page 43.)

Screening Effects Due to the Currents in the Tubes.

Before describing some further experiments on this shielding effect it will be useful to consider the means by which it is brought about. Let us suppose we have a vertical plate made of conducting material, and to the right of the plate a region, A, which it shields. This region has to be shielded from tubes of electrostatic induction coming from the left which have to pass through the shield before reaching A, and from tubes coming from the right which have to pass through A before reaching the field. The action of the shield in the first case is very simple, for when a tube gets inside a conductor it at once attempts to contract to molecular dimensions, and after a time proportional to the specific resistance of the conductor it succeeds in doing so. Thus if the shield is made of a good conductor the tubes of electrostatic induction will be transformed into molecular tubes before they have time to get through; so that the shield will protect A from all tubes which have to go through it. The way the shield destroys or rather neutralises the effect of the tubes coming from the right is somewhat different: when a positive tube reaches the shield a negative one emerges from it, travelling at right angles to itself in the opposite direction to the incident tube; thus when the first few tubes reach the shield from the right they will produce a supply of negative ones, and the presence of these negative tubes at A concurrently with the positive ones which continue to arrive there will weaken the field to a greater and greater extent as A approaches the shield. At the surface of the shield itself the neutralisation will be complete. A dielectric whose specific inductive capacity is greater than usual will behave in a similar way to a metal plate, but to a smaller extent. It will emit tubes of the opposite sign, but not so numerous as those incident upon it. Thus a metal plate, or even one made of a dielectric of considerable specific inductive capacity, will reduce very considerably the tangential electromotive force on either side it.

I have made several experiments in which this effect was very strikingly shown. In one of these two square discharge-tubes of equal cross-section placed near and parallel to each other were connected by a cross tube, so that the pressure was the same in both tubes; a fine wire passed round the inside of one of the tubes, its ends being connected together so that it formed a closed circuit, the other tube contained nothing but air at a low pressure. When this double tube was placed outside the primary the discharge went, at the passage of each spark, through the tube without a wire, while the tube containing the wire remained quite dark. A similar experiment was tried by taking a cylindrical tube and suspending in it a metal ring coaxial with the tube; in this case it was easy to adjust the spark-length so that no discharge passed through the tube when the primary was placed round it at the level of the ring, while a discharge passed as soon as the primary was moved above or below the ring.

Another very convenient tube for showing this effect is the one with the hollow down the middle, Fig. 11; when this is pumped so that discharges can pass through the outer tube the spark-length can be adjusted so that the discharge stops immediately when a metal tube, a test-tube containing a strong solution of an electrolyte, or a tube containing air at a pressure at which it is electrically very weak, is placed in the central opening. The discharge is renewed again as soon as the tubes are removed. On one occasion, when the large tube was in a peculiarly sensitive state, I was able to see distinctly the diminution produced by a dielectric in the electromotive intensity parallel to its surface. The discharge stopped as soon as a stick of sulphur or a glass rod sufficiently large almost to fill the opening was inserted, and was renewed again as soon as these were withdrawn. It requires, however, the large tube to be in an extremely sensitive state for the effect produced by a dielectric to be apparent, and I have only on one occasion succeeded in getting the tube into this condition. The effect on that occasion, however, was so definite and regular that I have no doubt as to the existence of the screening effect due to the dielectric.

When the tube is of average sensitiveness dielectrics do not produce any appreciable effect, nor can the influence of even comparatively so good a conductor as distilled water be detected, and it is not until after the addition of a considerable quantity, 10 to 20 per cent., of sulphuric acid or ammonium chloride, that the insertion or withdrawal of the tube stops or starts the discharge.

A tube containing air at a low pressure is very efficacious in stopping the discharge, and the result of the comparison of the relative effects of an exhausted tube and a tube of the same size and shape containing a solution of an electrolyte are very remarkable. I found that an exhausted tube which contained air at a very low pressure (less than one-tenth of a millimetre) produced as much effect on the discharge in the outer tube as a tube containing at least 50,000 times as many molecules of ammonium chloride. This would be expressed in the language of electrolysis by saying that under the electromotive intensity to which it was exposed in this experiment the molecular conductivity of the gas is 50,000 times that of the electrolyte. The proportion between the number of air molecules and the number of molecules of an electrolyte, which produces an equal effect in stopping the discharge, depends upon the length of spark in the primary current, and so upon the electromotive force acting upon the air. The longer the spark the greater is the molecular conductivity of the air in comparison with that of the electrolyte. This indicates that the conduction through the air does not follow Ohm's law. This is what we should expect, as under large electromotive forces more molecules are split up and take part in the conduction of the electricity. This great conductivity of rarefied gases in those cases where the electricity has not to pass from metal, &c., into the gas are in striking contrast with the infinitesimally small values for the same property which are deduced from experiments on tubes with electrodes.

I was first led to suspect this high conductivity for rarefied gases by observing the appearance presented by the ring-discharge in bulbs; the ring, unless the pressure is exceedingly low, ceases at a distance of little more than 1 centim. from the surface of the bulb, this thickness of conducting gas being sufficient to screen off the electromotive intensity from the interior. From experiments which I had made on the screening effect of electrolytes (*Proc.* Roy. Soc. XLV., p. 269), I knew that it would require a very strong solution of an electrolyte to produce screening comparable with this. To compare the screening effects more directly than by the method just described I tried the following experiment:—The discharge-tube (Fig. 11) was pumped until the discharge passed through it very freely. An exhausted tube was then pushed down the central opening; it remained quite free from any visible discharge. The primary was now wound round a cylinder of the same diameter as the discharge-tube of Fig. 11, and this cylinder was filled with distilled water. When the tube, which had previously remained dark when placed in the exhausted discharge-tube, was immersed in the water, a brilliant discharge took place in it; and it was necessary to add about 25 per cent. of sulphuric acid to the water before the shielding effect of the mixture was sufficient to keep the tube dark. This experiment shows, perhaps, even more directly than the other the great conductivity of a rarefied gas under large electromotive forces when nothing but the gas is in the way of the passage of the current.

An experiment made in this connection illustrates the remark made before as to the large effects produced by discharges through

* Abstract from the *Phil. Mag.*, October, 1891.

Digitized by Google

the gas which are not accompanied by luminosity. A bulb, A, was fused into a tube, B, which was surrounded by the primary coil C, D. B was exhausted and then sealed off, while A was left connected to the pump. When A was at atmospheric pressure a bright discharge took place in B outside A; on pumping A a stage was reached in which no discharge could be seen in either A or B. On letting air into A the discharge appeared again in B; on pumping A still further a discharge appeared in A, but not in B. The appearance presented by the discharge round the bulb A (filled in this case with air at high pressure) is very remarkable. At the highest pressure at which the discharge passed it took the form of

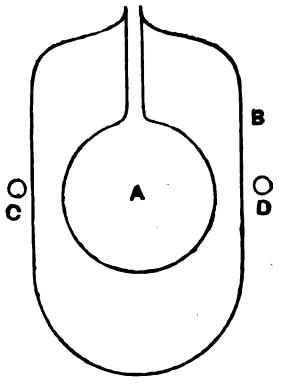


Fig. 13.

a thin ring round the middle of A; as the pressure got lower and lower the discharge broadened out, and at very low pressures formed for the greater part of its course two separate rings which ran together in the space between one side of the sphere and the tube.

(*To be continued.*)

DESCRIPTION OF THE STANDARD VOLT AND AMPERE-METER USED AT THE FERRY WORKS, THAMES DITTON.*

BY CAPTAIN H. R. SANKEY AND F. V. ANDERSEN.

1. Introductory.

It is well known to many electricians that Messrs. Willans and Robinson have established at their works at Thames Ditton a complete arrangement for measuring accurately the steam consumption of their engines. To obtain the efficiency of combined sets of engines and dynamos, measurements must, of course, also be made of the electric current and pressure, and it was thought that even the best ammeters and voltmeters in the market could not be relied upon to give the same degree of accuracy as was obtained in the steam-consumption measurements. At any rate, all such instruments laboured under the disadvantage that they were calibrated elsewhere, so that the results were dependent upon other people's measurements to a degree which was thought to be undesirable.

After a series of investigations—commenced as early as 1887—into the question of the class of apparatus which would be most likely to give satisfactory results under the special circumstances, a scheme was drawn up in 1889 for a complete apparatus for measuring currents, differences of potential, and resistances, and the various instruments were designed and ordered. It was not, however, until the beginning of the present year that time and opportunity were found to have the apparatus put to practical use, various additions and improvements being introduced as the work proceeded. It is well to mention at once that the results obtained with this apparatus are in practical agreement with those obtained with the Siemens dynamometers previously in use.

As will be seen in the sequel, no new principles have been introduced in electrical measurements with the present apparatus. It was thought, however, that a complete set of workshop instruments, fulfilling the conditions for high accuracy, and yet possessing the simplicity required for everyday use in an engineer's shop, would be found of sufficient interest to electrical engineers to justify a short account of it being brought before the Institution.

The more important conditions imposed in designing the apparatus were that—

1. All measurements made must be capable of verification at any time by direct comparison of certain resistance coils with a standard ohm, and of a constant potential difference with a standard cell; and that the arrangements should allow of these comparisons being made quickly for the satisfaction of those interested in the accuracy of the measurements.

2. Volts and amperes must be indicated by direct deflection on a scale, and no balancing operation be required from the observer by torsion arrangements or otherwise; and the value of the readings must not be influenced by the working of dynamos or the moving of large masses of iron within a few yards distance.

3. The ammeter as well as the voltmeter must be left in circuit permanently during trials of any desired length.

4. The errors to which the measurements are liable should not exceed one-fifth per cent.

5. The range such as to allow of measurements being made of pressure from a thousandth part of a volt to 700 volts, and of current from a fortieth of an ampere to 1,100 amperes.

2. Apparatus Required.

The complete apparatus comprises the following :—

I. *For Measuring Amperes.*

One D'Arsonval galvanometer.
One high-resistance box, adjustable by the unit, for use in series with galvanometer.
One rheostat of platinoid strips for carrying the main current (called resistance B).

II. *For Measuring Volts.*

One D'Arsonval galvanometer.
One high-resistance box, adjustable as above, for use in series with galvanometer. A Wheatstone bridge box is used for this purpose.
Three potentiometer rheostats, 250 ohms each, made of platinoid wire on screwed slate rods, carrying capacity up to 1 ampere.

II.—*For Calibration.*

One Clark standard cell containing two elements.
One standard ohm.
One standard rheostat of five platinoid strips, arranged for coupling in parallel or series, each strip capable of carrying 10 amperes (called resistance A).
One mercury rheostat, capacity 50 amperes.
One secondary battery, three large cells (15 L. E.P.S.).
One key with double set of contacts, for use with standard cell.
One resistance coil, 10,000 ohms, for use with same.
Two $\frac{1}{9}$ shunts for galvanometers.

IV.—*General.*

Leclanché cells for bridge test, keys, ebonite pillars for connections, &c.

The method of using the apparatus for actual measurements will first be described, after which the calibration of the galvanometers and the verification of the various resistances will be discussed.

3. Measuring Amperes.

The apparatus used for this purpose is shown on Fig. 1* with the connections in dotted lines. On the same figure is drawn the voltmeter arrangement, in order to give the general arrangement of the

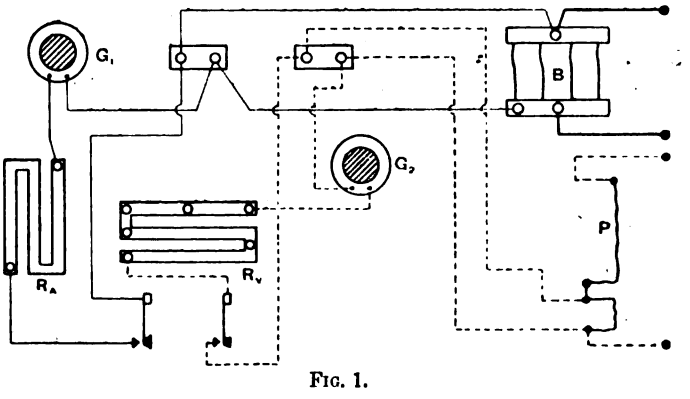

Fig. 1.

whole set of instruments; the circuits of the voltmeter arrangement are in black. It will be seen on Fig. 1 that for current measurements the method of measuring the fall of potential across a known resistance has been adopted. The measurement of this resistance—*i.e.*, the resistance of rheostat B, Fig. 2 and Fig. 1, which, of course,

* Paper read before the Institution of Electrical Engineers.

* We have taken the liberty of renumbering the figures in the order in which they are referred to.—Ed. *E.*

Digitized by Google

must be made with great accuracy—could not be taken satisfactorily by a Wheatstone bridge, owing to its small value (about ·001 ohm); the method adopted for this purpose will be described further on.

The scale of the D'Arsonval galvanometer, G_1, has, in addition to the ordinary millimetre scale, another scale graduated to read from 0 to 1,100 amperes, on which the divisions are proportional to the corresponding currents through the galvanometer, the relation or constant connecting the deflections with this current being known from the calibration of the galvanometer.

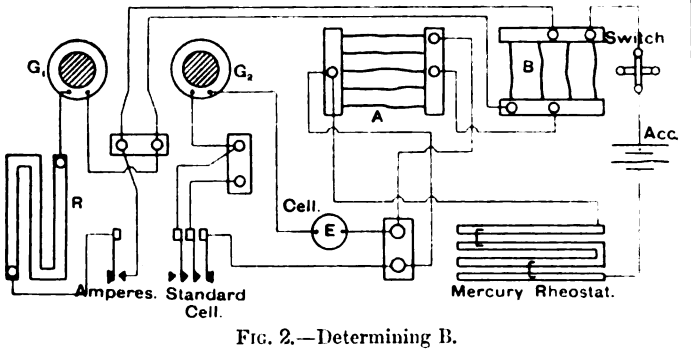

FIG. 2.—Determining B.

By modifying the resistance, R_A, used in series with the galvanometer, the constant of the ammeter can be modified to suit the number of amperes to be measured. If

k = current through G per unit deflection on ampere scale;
K = ,, ,, B ,, ,, ,, ,,
B = ohms resistance of B;
G = ,, ,, of galvanometer;
R_A = ,, ,, in series with galvanometer:

then for any deflection, D, on the ampere scale $(G+R)\,k\,D = K\,D\,B$;

and so $$R_A = K\,B/k - G \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

In the present case we have,

B = ·0010882 legal ohms at standard temperature, 17°C.
G = 429 ,, ,, ,, ,,
$k = \cdot 06 \times 10^{-6}$ amperes;

and, therefore, the resistance R to be used in series with the galvanometer to obtain different ammeter constants = K × 18,137 − 429 legal ohms.

Table I. gives the constants in use, and the corresponding values of R.

Table I.

Ammeter constant K.	R_A in legal ohms.	Correction legal ω per °C of rise in B.	Remarks.
1	17,708	4·17 + γ	Rise in B.
0·5	8,639	2·09 + γ	$= C^2 \times 2 \times 10^{-5}$ °C.
0·1	1,385	0·417 + γ	γ = 1·66 (17 − t).
0·025	24	0·0417 + γ	t = temp. of G in °C.

The following are the corrections for temperature which must be made in R in order to get the accuracy desired:—

(1.) For the galvanometer, at the rate of 1·66 ohms per degree Centigrade variation from the standard temperature—in this case 17° C.

(2.) For the rise in B due to the current at the rate of ·023 per cent. per degree Centigrade, the amount of resistance per degree is given in the third column of the table; and the constant for calculating, from the current, the rise of temperature in B, as determined by experiment, is given in the fourth column.

When the main rheostat, B, is made from the same metal and placed in the same room as the resistance box R_A, the periodic temperature variations in the atmosphere do not affect the measurements of the current through the increase of the resistances of these two instruments, as the increase in one balances that in the other.

For ordinary work the readings on the scale are amply accurate, as they can be depended upon to be within ·3 per cent. of error.

For very accurate trials, however, the scale is used only to ensure the practical steadiness of the load, and for taking readings at short intervals in order to obtain the mean reading. The current corresponding to this mean reading is then determined by direct comparison with the standard ohm and cell.

This determination of the current is made by substituting in the galvanometer circuit an E.M.F. equal to that of the standard cell for the potential difference on the terminals of B, and then, by shunting the galvanometer and adjusting R_A, reproducing the deflection in question. If, then,

C = the current to be determined;
G = the resistance of the galvanometer;
R_1 = the resistance in series with G when standard cell is in circuit;
R_A = the resistance in series with G when B is in circuit;
e = the E.M.F. of standard cell;

and if the shunt is of a multiplying power = m: then

$$C = \frac{R+G}{m R_A + G}\,\frac{e}{B} \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

(To be continued.)

DINNER OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

The third annual dinner of the Institution of Electrical Engineers was held at the Criterion, Piccadilly, on Friday last; the President (Prof. Crookes) in the chair. Amongst those present were:—Sir George Gabriel Stokes, Bart., M.P.; Mr. George Berkly (President of the Institution of Civil Engineers); Mr. Latimer Clark (past President), Mr. W. H. Preece (past President), Sir Frederick Abel, K.C.B.; Prof. W. Grylls Adams, Sir John Pender, K.C.M.G.; Sir Benjamin Baker, K.C.M.G.; Sir Thomas Blomefield, Bart.; Prof. D. E. Hughes, Dr. Fleming, Captain Wharton, R.N.; Major Cardew, R.E.; Mr. Edward Graves, Colonel W. Haywood, Major G. W. Addison, R.E.; Mr. C. E. Spagnoletti, Major-General Webber, Colonel R. Raynsford Jackson, Sir David Salomons, Bart., &c., &c.

The PRESIDENT announced that they had to regret the absence of several guests. The Postmaster-General had accepted an invitation, but was at the last moment obliged to decline, not being sufficiently well. Amongst others who expressed their regret at not being able to join them were Mr. Tomlinson (the President of the Institution of Mechanical Engineers), Mr. Giles, M.P. (Vice-President of the Institution of Civil Engineers), Dr. Pool (Hon. Sec. of the Institution of Civil Engineers), and Dr. John Hopkinson.

After the usual loyal toasts, the PRESIDENT rose and proposed the toast of "Electricity in relation to Science." He said:—We have happily outgrown the preposterous notion that research in any department of science is mere waste of time. It is now generally admitted that pure science, irrespective of practical applications, benefits both the investigator himself and greatly enriches the community. "It blesseth him that gives and him that takes." Between the frog's leg quivering on Galvani's work table, and the successful telegraph or telephone there exists a direct affiliation. Without the one we could not have the other. We know little as yet concerning the mighty agency of electricity. "Substantialists" tell us it is a kind of matter. Others view it, not as matter, but as a form of energy. Others, again, reject both these views. Prof. Lodge considers it "a form or rather a mode of manifestation of the ether." Mr. Nikola Tesla demurs to the view of Prof. Lodge, but thinks that "nothing stands in the way of our calling electricity ether associated with matter, or bound ether." High authorities cannot even yet agree whether we have one electricity or two opposite electricities. The only way to tackle the difficulty is to persevere in experiment and observation. If we never learn what electricity is, if, like life or like matter, it should remain an unknown quantity, we shall assuredly discover more about its attributes and its functions. The light which the study of electricity throws upon a variety of chemical phenomena, witnessed alike in our little laboratories and in the vast laboratories of the earth and the sun, cannot be overlooked. The old electro-chemical theory of Berzelius is superseded, and a new and wider theory is opening out. The facts of electrolysis are by no means either completely detected or co-ordinated. They point to the great probability that electricity is atomic, that an electrical atom is as definite a quantity as a chemical atom. The electrical attraction between two chemical atoms being a million times greater than gravitational attraction is probably the force with which chemistry is most deeply concerned. It has been computed that in a single cubic foot of the ether which fills all space there are locked up 10,000 foot-tons of energy which have hitherto escaped notice. To unlock this boundless store and subdue it to the service of man is a task which awaits the electrician of the future. The latest researches give well-founded hopes that this vast storehouse of power is not hopelessly inaccessible. Up to the present time we have been acquainted with only a very narrow range of ethereal vibrations, from extreme red on the one side to ultra-violet on the other. Within this comparatively limited range of ethereal vibrations, and the equally narrow range of sound vibrations, we have been hitherto limited to receive and communicate all the knowledge which we share with other rational beings. Whether vibrations of the ether, slower than those which affect us as light, may not be constantly at work around us, we have until lately never seriously enquired. But the researches of Hertz in Germany, and of Lodge in England, give us an almost infinite range of ethereal vibrations or electrical rays from wave-lengths of thousands of miles down to a few feet. Here is unfolded to us a new and astonishing

Digitized by Google

universe—one which it is hard to conceive should be powerless to transmit and impart intelligence. Experimentalists are reducing the wave-lengths of the electrical rays. With every diminution in size of the apparatus the wave-lengths get shorter; and could we construct Leyden jars of molecular dimensions, the rays might fall within the narrow limits of visibility. We do not yet know how the molecule could be got to act as a Leyden jar; yet it is not improbable that the discontinuous phosphorescent light emitted from certain of the rare earths, when excited by a high-tension current in a high vacuum, is really an artificial production of these electrical rays, sufficiently short to affect our organs of sight. If such a light could be produced more easily and more regularly, it would be far more economical than light from a flame or from the arc, as very little of the energy in play is expended in the form of heat rays. Of such production of light, nature supplies us with examples in the glow-worm and the fire-flies. Their light, though sufficiently energetic to be seen at a considerable distance, is accompanied by no liberation of heat capable of detection by our most delicate instruments. By means of currents alternating with very high frequency Mr. Nikola Tesla has succeeded in passing by electrostatic induction through the glass of a lamp energy sufficient to keep a filament in a state of incandescence without the use of connecting wires. The extent to which this method of illumination may be practically available experiment alone can decide. In any case, our insight into the possibilities of static electricity has been extended, and the ordinary electric machine will cease to be regarded as a mere toy. Alternating currents have, at the best, a rather doubtful reputation. But it follows from Tesla's researches that as the rapidity of the alternation increases they become not more dangerous, but less so. It further appears that a true flame can now be produced without chemical aid—a flame which yields light and heat without the consumption of material and without any chemical process. To this end we require improved methods for producing excessively frequent alternations and enormous potentials. Shall we be able to obtain these by tapping the ether? If so, we may view the prospective exhaustion of our coal fields with indifference. We shall at once solve the smoke question, and thus dissolve all possible coal rings. Electricity seems destined to annex the whole field, not merely of optics, but probably also of thermotics. Rays of light will not pass through a wall, nor, as we know only too well, through a dense fog. But electrical rays of a foot or two wave-length, of which we have spoken, will easily pierce such media, which for them will be transparent. Another tempting field for research, scarcely yet attacked by pioneers, awaits exploration. I allude to the mutual action of electricity and life. No sound man of science endorses the assertion that "electricity is life," nor can we even venture to speak of life as one of the varieties or manifestations of energy. Nevertheless, electricity has an important influence upon vital phenomena, and is in turn set in action by the living being—animal or vegetable. In the study of such facts and such relations the scientific electrician has before him an almost infinite field of inquiry. The slower vibrations to which I have referred reveal the bewildering possibility of telegraphy without wires, posts, cables, or any of our present costly appliances. It is vain to attempt to picture the marvels of the future. Progress, as Dean Swift observed, may be too fast for endurance. Sufficient for this generation are the wonders thereof (applause). I have the pleasure to associate this toast with the name of Sir George Stokes. We expected that Sir Wm. Thomson, the President of the Royal Society, would have been here; but in his absence we could not have a better representative of science in all its branches, electrical and every other science, than Sir George Stokes.

Sir GEORGE STOKES, in responding, said among the various individual sciences there was hardly any to compare with electricity in two respects, viz., in the multitudinous points of contact which it had with other sciences, apparently remote, and in the remarkable way in which abstract theoretical investigations found their application in actual practice. It was very closely connected with chemistry. The discovery of Faraday of the law of electro-chemical equivalents showed how close that relationship must be. What was an electric current? They did not know. Whatever it was, it must, however, be in some way or other very closely associated with chemical union and decomposition. Then, again, to take light: they knew in some respects a great deal more about light than they did about electricity. About 39 years ago he happened to be sitting at dinner during a meeting of the British Association beside the illustrious Faraday; and he said to Faraday that "he thought a great step would be made if we could say as much of electricity as we could say of light, when we said that it consists of vibrations," and Faraday said to him that "he thought that we were yet a long way off from that." Nevertheless, the connection between light and electricity had been rendered much more close by recent researches; first came that great discovery of Clark Maxwell's, and then the remarkable investigation of Hertz.

Mr. C. E. SPAGNOLETTI, in giving "Electricity in its Practical Application," treated upon the usefulness of electricity and its convenience to every class of the community in all quarters of the globe.

Sir JOHN PENDER replied. He could not, he said, give them any information from the high scientific point of view, but he could say something in reference to the practical application of electricity. He had been for the last 30 years more or less associated with this important want. When he first had to do with submarine telegraphy there was not two thousand miles of cable laid. Now there was over 130,000 miles of cable laid, representing a capital of over 40 millions; and that capital had been got from the public, and a very large proportion of it was paying a healthy dividend. There was also about two million miles of land lines. He did not touch upon them so much because he was not so closely associated with them, although he was one of the first directors of the land line system in this country. Amongst those associated with him in the earlier days of electricity was Mr. Latimer Clark, who continued to be their practical adviser on all the cable companies with which he was connected. Then his friend Sir William Thomson had a lively appreciation of what science could do if properly handled by practical men; and it was through Sir William that he took up submarine telegraphy, which now occupied a position second to none in the world. He believed it had done more to promote human progress in the last quarter of a century than any other thing that had been brought forward. They had now through the application of Dr. Muirhead's duplex system to their telegraphs practically doubled the carrying power of their cables; in other words, if they had to lay down to-day the cables necessary to carry on the cable traffic without the duplex system, it would add at least 20 millions more to their capital. That duplex system applied to submarine telegraphy had proved an enormous success in the hands of practical men. With reference to the electric light he remembered looking at it as a laboratory experiment; and then for nine years he saw an enormous amount of money spent foolishly in connection with it. He said to two or three of his friends, "We ought to deal with this electric light, we have dealt successfully with telegraphs; let us endeavour to bring it into a practical form." He thought they had been successful in doing that. He was proud to say that the electric light was now upon a basis which he had not the slightest hesitation in saying must be a very great practical improvement. When he first took up telegraphs he did not know half-a-dozen men who called themselves electrical engineers. That was only a quarter of a century ago; and he believed now that the Institution of Electrical Engineers mustered something like 2,000 members. Surely that marked enormously the success of electrical science, coupled as it had been with commercial energy and commercial foresight. There was a great deal to be done yet in the electrical field. He did not know any field so broad or more encouraging for young engineers as electricity. Representing as he did telegraphs and electric lighting companies, if there was any man who could bring something to him which would enable him to add 1 per cent. to the dividend they were now paying, he should be only too glad to treat with him. The President had said that there was a time coming when possibly we could do without wires and other costly appliances. He wished that that good time would come before he died, for at present the power they used was enormously expensive. If they could only reduce the expense in some degree there was no conception as to the extent to which it could be applied. With regard to the electric light, for instance, there were but some 300,000 lights in London, and if they had three million lights they would not be too many. It was for the electrical engineers to give the capitalists something to turn to practical account, and it would be rapidly taken up (loud cheers).

Mr. W. H. PREECE next gave "Our Guests," coupled with the name of Mr. George Berkly, the President of the Institution of Civil Engineers, who responded.

In proposing "The Institution of Electrical Engineers," Sir GEORGE GABRIEL STOKES said it was remarkable how little they knew of the real nature of electricity in itself, and yet how much they had applied it for practical purposes. They could hardly help believing that if they attained to a more intimate knowledge of what its real nature was applications would spring up of which at present they had little idea. Their President's discovery of the radiometer gave them a clear conception of the molecular constituents of bodies, and especially gases. They appeared to be on the brink of some great discovery, and this ought to make them feel an interest in their work.

The PRESIDENT, in reply, said that he felt perplexed how best to respond to the very kind way in which Sir George Stokes had mentioned his name, and the manner in which they had received it. The toast was an important one, and he had prepared a speech, which he did not feel justified in inflicting upon them at that late hour of the evening.

We give the text of the speech:—Without unjustifiable vanity I may be allowed to say that the Electrical Engineers have abundantly justified their existence. But instead of smooth prophecies or perching on the highest "dead" wire and crowing, it may be better to take a bird's eye view of the solid work that lies ahead. I have already referred to certain unsolved problems of electric energy. In the list of momentous problems the action of electricity on animal and vegetable life is not the least important. As regards the treatment of disease, the subject is temporarily overclouded by falling into the hands of advertising quacks. In respect to vegetation, it is still uncertain whether electrical currents exercise any decided or uniform influence upon growing crops of grain and fruit; whether such influence would be favourable or the reverse. Recent experiments lead to the opinion that electricity may induce earlier and better harvests. But much further study is here needed. Nor have we yet solved the equally important and closely connected question, whether we may by electrical action rout the parasitical insects and fungi which in some seasons rob us of no less than the tenth of our crops. A moderate estimate puts the mean loss in the home kingdoms at £12,000,000 per annum. In India and the Colonies a number of destroyers, which it is not my business to specify, are less easily contented. Like Falstaff, in the words of Dame Quickly, they seek to take "not some, but all." The attacks of the phylloxera have cost our French neighbours more than did the Franco-Prussian war. It has been found in not a few experiments that electric currents not only give increased vigour to the life of the higher plants, but tend to paralyse the baneful activity of parasites, animal and vegetable. Here there is unlimited scope for practical research, in which the electrical engineer must join forces with the farmer, the gardener, and the vegetable physiologist. We have definitely to decide whether, and under what circumstances, electricity is beneficial to our crops, and whether, and under what conditions, it is deadly to parasitic pests. Here, then, comes the question of a supply of electricity cheaper and more universally applicable than the tedious conversion of chemical energy into heat, of heat, again, into mechanical power, and of such power into electric current. It is depressing to reflect that this roundabout process, with losses at every step, is still our best means of obtaining a supply of electricity. With regard to the possible applications of electricity to agriculture, I may mention that the total amount of *vis viva* which the sun pours out yearly upon every acre of the earth's surface, chiefly in the form of heat, is 800,000

Digitized by Google

H.P. Of this mighty supply of energy a flourishing crop utilises only 3,200 H.P., so that the energy wasted per acre of land is 796,800 H.P. We talk loudly of the importance of utilising the refuse of our manufactures; but what is the value of alkali waste, of furnace slags, of coal tar, or all of them together, compared to the loss of 796,800 H.P. per acre of land? The application of electricity to sanitary improvements is another possibility, turning mainly on a cheap supply of current. The electric treatment and purification of sewage and industrial waste water is a demonstrated reality which merely requires a reduction in the cost of the agent employed. The sterilisation by electrical means of the water supply of cities has been proposed and discussed. Theoretically it is possible, but the practical difficulty of dealing with the vast volumes of water required for the daily consumption of London is prodigious. But a difficulty, said Lord Lyndhurst, is a thing to be overcome. There is a still more important consideration; the living organisms of water are by no means all pathogenic. Many are demonstrably harmless, and others possibly beneficial. Before the sterilisation of our water sources can be prudently undertaken, this great question must first be decided by experimental biologists. Another point at which the practical electrician should aim is nothing less than the control of the weather. The question is, cannot the accumulations of electric energy in the atmosphere be thwarted, dispersed, or turned to practical use? In like manner we may hope to abate the terrible fog nuisance. Nature supplies energy amply sufficient. How is this prodigious quantity of power to be made available? These are problems that may safely be left to the devices and inspirations of our electrical engineers. I have given you some indication of the intricate problems to be handled, of enormous difficulties to be surmounted. What is really in store in the way of future wonders is folded "in shady leaves of Destiny."

CORRESPONDENCE.

THE USE OF ELECTRIC MOTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I read with mixed interest and disappointment your article of October 30th on the use of electric motors. Whilst you are entitled to the thanks of electrical engineers for drawing attention to this important matter, yet I must confess that I think you have been unfortunate in your treatment of the subject. Many of your readers who have not closely followed the subject will put down your article with the sense that, after all, the use of electric motors will be extremely limited. I cannot hope that my letter will be as widely read as your article, still I wish by putting the following on record to show that the case is not as you put it. The mistake you have made throughout is a very common one, viz., you estimate the cost of working the system at the cost of only one of its items. In comparing the cost of gas motors with electric motors you have set the cost of gas against that of electricity, as if this alone would determine the choice of the intending user.

If you study the interesting question of the introduction of labour-saving machinery, whether for the generation of energy or for its utilisation, you will find that the first question put by an intending user of a labour-saving appliance is not what will be the cost of power and attendance required to run it, but what will be its first cost, and in what time may he expect to repay this first cost by the economy it introduces. If a maker of a combined wood-sawing and moulding machine to be worked by gas or electric power wished to push its sale amongst the smaller class of London furniture-makers, who have hitherto entirely trusted to hand labour, the first advantage he would claim for the electrically-driven plant would be that it would only cost £40, whereas the plant driven by a gas engine could not be put down under £160. He would then call attention to the case of starting and stopping, and hence the comparative handiness of the electrically-driven plant, and would certainly point out that the time during which the power would be required would be so short that the difference of cost of gas and electricity would not tell prejudicially against the electric motor.

The whole subject of the "load factors" of machine tools is a very interesting one to mechanical as well as electrical engineers. Of course I use "load factor" in the sense that I used it in my Paper read before the Institute of Civil Engineers on the cost of electrical energy; but to those who have not read that Paper I must explain that I mean by "load factor" the proportion that the total number of hours at which any plant is worked at full load bears to the total number of hours in the year. Very few people have taken the trouble to calculate how many hours the various classes of labour-saving machinery are kept at work and absorbing power; but I believe it will be generally admitted that the class of tools which it is intended to drive by electrical motors are used very intermittently, so that the actual hours during which they take power rarely exceeds 300 per annum. It follows that the cost of the power itself during this small number of hours bears quite a small proportion to the percentage costs, such as interest on capital outlay, repairs, &c. This fact tells very strongly in favour of motors, which cost little in the first instance, even if they are costly in their use of energy; but I go a step farther, and challenge the accuracy of your statements of the comparative cost of gas and electricity during the times that both classes of motors are actually at work. The figure you give of 1d. per hour for a small gas engine is misleading. In all probability it would be found that most gas engines are not worked intermittently, but are run for long hours very lightly loaded. This fact alone increases the average cost of the power (*i.e.*, divided over the time that they are actually doing useful work) from 1d. up to 3d. or 4d. If the cost of oil, cleaning, material, and the extra cost of attendance is added to this, in all probability the annual bill for electricity and attendance on the intermittently-worked electric motor will be found less than the annual bill for gas, oil, and attendance on the gas engine. Of course much depends on the number of hours during which the motor is used. For continuous work, such as ventilation, pumping water, driving electric lighting plant, or the like, the gas engine is undoubtedly the cheapest; but for most of the intermittent work for which machine tools are used, such as cutting wood, metal, or stone, or polishing gems, weaving, sewing, embroidery, and the like, the electric motor will be found to surpass its rival in every point. I think some of us who have had considerable experience in these matters are beginning to realise the fact that the field of the electric motor will extend into the mechanical workshop, and that the long lines of shafting at present used will be superseded by a system of driving each machine tool by its own separate motor. Such a change will result in great convenience of arrangement to our workshops, and in great reduction of the cost of the energy used.—I am, &c.,

R. E. CROMPTON.

Mansion House Buildings, London, E.C., Nov., 18, 1891.

THE THEORY OF THE WIMSHURST MACHINE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In answer to your Note of the 6th inst., allow me to say that I was led to enunciate this attempt at a theory of the Wimshurst machine while translating Gray's book on "Electrical Influence Machines." The theory given by the author, I now see, is no other than that of Prof. Thompson. I discussed the matter in *La Lumière Electrique* of October 10th.

Besides the difficulty one finds in explaining how it is produced, the *primitive* distribution of electricity on the plates—(+) on one half (−) on the other—does not seem to me worthy of acceptance, for the following reasons.

This theory does not take in account at all how the machine works when it is primed by the influence of a foreign body placed in front of a brush, β for example. You know that in this case, according to the sign of the influencing body, the direction of the current may be reversed. It is impossible in this instance to assume the pre-existing charge, and we are led to conclude that the action of the machine consists precisely in establishing the known electrical distribution.

It was the mechanism of this distribution that I sought to explain, for it is in it that the whole action of the machine seems to me to reside, since the growth of the charges is merely the consequence of the electrifications established. To assume that this distribution exists on the plates independently of the action of the apparatus seems to me to be a very imperfect way of explaining the phenomena.

I regret having to insist so much on this point, and having to trouble you with claims which have only a personal bear-

Digitized by Google

ing; but I think it would be of interest to definitely settle the theory of the Wimshurst machine, and I shall be very happy if this discussion contributes to that end.—I am, &c.,

Paris, November 18, 1891. G. PELLISSIER.

THE MAGNETIC (*SIC*) LADY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As many of your readers may not have seen my letter in the *Times*, they may be interested to know that at any rate the above performance is a perfectly genuine one, no assistance whatever being given to the lady, and her force is distinctly self-contained.

I am by no means a stranger to the Alhambra stage, and I think that if it had been any question of stage trickery the Directors would hardly have asked me, at any rate, to have gone on the Committee.

From the earlier tests I was at first inclined to believe that it was only some process of hypnotic suggestion; and as I do not approve of mesmerizing performances, I took no active part in withstanding the lady's prowess. The subsequent tests, however, were of a totally different order, as the force exerted in many instances must have been enormous, and, as I had hold of the lady's fleshy, but not muscular, arm on several occasions, I can safely say that muscular power was not brought into play, the biceps remaining quite supple.

To me the most interesting experiments were those in which the force was not exerted direct on the object, and on as many occasions as I could I placed my palm between Miss Abbott's hand and the chair or cue. The lady did not touch the object except through my hand, and although I kept this motionless I endeavoured to exert an active influence the reverse direction of what was desired. On the occasion when she moved off the ground the two chairs with six heavy men on them, and when from the great trembling of her arms some great force must have been brought into play (although her muscles were inert), I felt a vibratory agitation through my hand somewhat similar to what I have on certain occasions experienced when near a powerful dynamo.

Surprise has been expressed that the billiard cue did not break when three or four men were pushing against it; but I would point out that objection was taken to anyone placing their two hands side by side, as the lady did not appear able to exert any power against the particular "circuit" thus formed by one body. By thus distributing the hands the strain was not so much at the ends of the cue, and the force and weight were more spread over the centre of it; however, on the occasion of the four men attempting to force back the cue it bent to almost breaking point.

Unless one has been so intimately associated with the performance as I was, it is quite impossible to understand the profound impression it produces, and certainly the whole exhibition is of far greater scientific and general interest than any of the objectionable mesmerism entertainments that have recently become so frequent.

I believe it is intended on every occasion to have gentlemen from the audience on the stage, and I am sure the management would give a preference to any electrical engineer at all well known who desires to have an opportunity of thus closely watching the performance.—I am, &c., JOHN B. VERITY.

November 17, 1891.

RAILWAY RATES AND CHARGES.*

The appended particulars are prepared to show the chief results attained by the London Chamber of Commerce and other bodies in their opposition to the original proposals made by the various railway companies under the Railway and Canal Traffic Act, 1888. The schedule to the London and North-Western Provisional Order Act is selected as being that upon which Parliament chiefly grounded its action. Those who have had any connection with the various proceedings resulting from the General Act are aware of the immense amount of detail involved in the discussion, while outsiders may gain some idea of the cost entailed in a Parliamentary procedure of this kind when it is stated that the expenditure of the London Chamber alone has been nearly £2,000. On the whole the results attained, when compared with the pretensions of the railway companies as indicated in their original proposals, must be considered as satisfactory, although, perhaps, the limit originally laid down by the Board of Trade, namely, that of the present actual charges of the companies, has not been quite attained in the statute. Taken generally, it will be found that the Provisional Order Acts practically limit the maximum charging powers of the companies in respect of the various classes in which the goods and merchandise are arranged to those exercised under the Railway Clearing House regulations. If the powers conferred on the companies had been limited to the actual rates the trading community would not have been in a position to make any adverse criticism; but to these rates must be added the charges which the companies are allowed to make under the head of station and service terminals. These will involve a considerable increase on the rates charged under the various classes; but even with their addition, it must be recognised, in fairness to the Board of Trade, that the present powers of the companies are, in comparison to the powers which they held previously, very materially reduced. As far, therefore, as these reductions go, the trading community can claim that they have obtained a practical result in their opposition to the Railway Companies Bills.

The following items are worthy of perusal in detail, the respective gains they show, as compared with what would have been obtained by the companies had their first propositions been sanctioned, being apparent at a glance.

ARTICLE.	Railway Clearing House.	Original Proposals L. & N. W. R.	Provisional Order Act.

Where a gain compared with the proposals of the Railway Company has been registered in the Provisional Act, this is shown by the use of a blacker type.

TRADE NOTES AND NOTICES.

NOW READY.—"THE ELECTRICIAN" PRIMERS (38 in all. Vol. I., 20; Vol. II., 18), in two volumes. Price per volume 2s. paper covers, 2s. 6d. cloth; post free, 2s. 2d. and 2s. 9d. respectively. Single copies, 3d.; post free, 3½d. Prospectus on application to the Publisher.

SALES BY AUCTION.—Our advertisement columns contain particulars of the sale by auction by Messrs. Wheatley Kirk, Price, and Goulty, on Wednesday, December 2nd, of the engines, boilers, shafting, machinery, &c., belonging to the International Cotton Waste Company, Limited (in liquidation), 449, Old Ford-road, London, E.

——— The valuable stock of new and exhibition engines of the Beck Gas Engine Company, Limited (in liquidation), together with the British and Colonial patents, &c., are to be sold by auction at the County Hotel, Newcastle-on-Tyne, on Wednesday,

* From the *Journal of the London Chamber of Commerce*, Nov 10, 1891.

Digitized by Google

December 9th. Further particulars appear in our advertisement columns.

TENDERS ACCEPTED.—The Corporation of St. Helens have, in connection with the proposed electric lighting of the Town Hall, accepted the tenders of Messrs. Bumsted and Chandler, of Cannock Chase Foundry and Engine Works, Hednesford, Staffs., for supplying the engines, dynamos, and boilers, at £864; and of Messrs. J. D. F. Andrews and Co., 41 and 42, Parliament-street, London, &c., for the necessary wiring, at £419.

REMOVAL NOTICES.—Messrs. Appleton, Burbey and Williamson have removed to 92, Queen Victoria-street, London, E.C.

——— Messrs. Barnett, Wynne, and Barnard have taken possession of their new premises, Volt Works, Walker, Northumberland.

NEW FIRM.—Mr. Robt. W. Paul, who was formerly with Messrs. Elliott Bros., informs us that he has taken workshops and office at 44, Hatton-garden, E.C., and has commenced business as electrician and scientific instrument maker. Mr. Paul took the Honours Medal of the City Guilds for instrument making in 1887.

DISSOLUTION OF PARTNERSHIP.—Messrs. Arthur B. Gill and Co., electrical engineers, of 36, Parliament-street, Westminster, and Bermondsey, have dissolved partnership. The business will, we understand, be carried on by Mr. Arthur B. Gill alone.

MESSRS. EDLIN AND STEVENSON.—We learn that Messrs. Edlin and Stevenson have now settled down in their new premises at Cape Town. Their offices are situated in Alderley-street, and their stores at Church-street. Telegraphic address, "Electrical, Cape Town."

ELECTRIC LIGHTING AT LIVERPOOL.—With reference to our Note of last week *re* electric lighting of Messrs. Henschberg and Ellis's new premises, we are informed that the work was carried out to the specification and under the superintendence of Mr. T. L. Miller, consulting electrical engineer, 7, Tower-buildings, Water-street, Liverpool. The large main switchboard used in the installation was supplied by Munro's Manufacturing Company.

DROITWICH.—The electric bells at the recently-opened Worcestershire Brine Baths Hotel at Droitwich were fitted up by Mr. E. H. Hill, of Birmingham.

MESSRS. J. G. STATTER AND CO., LIMITED (IN VOLUNTARY LIQUIDATION).—A meeting of the shareholders of this Company (which, as our readers will remember, became absorbed in the Electrical Engineering Corporation, Limited) will be held at 3, Prince's-mansions, Victoria-street, S.W., on December 19, at 1 p.m., to receive the liquidator's account of the winding up.

MESSRS. DRAKE AND GORHAM.—This firm have just installed the electric light at Felsted, which is the first public school in the country to be so lighted. The electricity is generated by a double set of engines and dynamos, and there is an accumulator battery of 53 cells. Three hundred and eighty-five Swan-Edison incandescent lamps are used to light the school buildings.

ALLCHIN, LINNELL AND CO. (LIMITED).—The public examination in this matter has been appointed for November 25th, at 11, at 34, Lincoln's Inn-fields.

THE FIRE AT MESSRS. LAING, WHARTON AND DOWN'S.—Messrs. Laing, Wharton and Down inform us that a disastrous fire occurred on Tuesday night at their works. They are, however, making arrangements which will enable them to execute orders as promptly as ever if customers will kindly give them their indulgence and a few days' grace.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

October 5, 1891.

16,870. T. SUTCLIFFE and E. H. ATKINSON. London. Improvements in the combination of electrical brush, brush-holder, and lubricator.

16,875. J. GRANT. Glasgow. Improvements in automatic electrical apparatus for signalling and preventing accidents on railways.

16,895. J. B. SPURGE. London. Improvements in electric arc lamps.

16,931. E. C. GRASSOT. London. Improvements in electric meters. [Date applied for under Patents Act, 1883, Sec. 103, 4th April, 1891. Being date of application in France.]

October 6, 1891.

16,934. H. H. LAKE. London. Improvements in secondary batteries. (P. Kennedy and C. J. Diss, United States).

16,938. H. H. LAKE. London. Improvements in secondary or storage batteries. (P. Kennedy and C. J. Diss, United States).

16,941. A. P. LUNDBERG. London. Improvements in switches for electric lighting.

16,958. H. A. MAYOR, W. A. COULSON, S. MAYOR and W. B. SAYERS. Glasgow. Improvements in or relating to metallic junction boxes or cases for conductors or fittings for electric lighting, electric bell circuits, and like purposes, and in the mode of connecting the conductors thereto.

16,989. H. H. LAKE. London. Improvements in printing telegraphs. (M. G. Farmer, United States).

16,991. F. H. W. HIGGINS. London. Improvements in type-printing telegraphic apparatus.

17,003. A. F. MADDEN. London. Machines for making grids for secondary batteries.

October 7, 1891.

17,032. T. SMITH and J. C. HALL. London. Duplex plates or discs fo electrical health appliances.

17,042. J. MACHAFFIE. Glasgow. Improvements in and relating to dynamo-electric machines applicable for the traction or propulsion of any vehicle, vessel, or body, as well as for all purposes to which dynamo-electric machines may be suitable.

17,074. J. C. REILLY. London. Improvements in electrical subways.

October 8, 1891.

17,107. J. H. RIDER. Halifax. Improvements in electric arc lamps.

17,118. T. TUBINI. London. Improvements in arc lamps.

17,119. W. C. CHEESEWRIGHT. London. Improvements in electrical switches.

17,148. W. B. SAYERS. London. Improvements in electrical switches.

17,160. H. H. LAKE. London. Improvements in and relating to electric accumulators. (La Société dite Electriciteits Mattschappij—Systeme de Khotinsky, Germany).

October 9, 1891.

17,192. A. WRIGHT. Brighton. Improvements in electric distribution.

17,220. S. Z. DE FERRANTI. London. Improved means and apparatus for commutating or rectifying an alternating current.

17,227. J. C. HOWELL. London. Improvements in electric cables.

17,231. SIEMENS BROS. AND CO. (LIMITED), J. NEBEL and F. H. VALTER. London. Improved winding for drum armatures of dynamos and electromotors.

October 10, 1891.

17,264. J. RICH. London. An improved self-winding electric clock.

17,291. W. MITCHELL. London. Improvements in electric soldering irons.

17,310. L. VON ORTH and E. BRESLAUER. London. Electric signalling apparatus for use with a network of electrical lines or conductors

SPECIFICATIONS PUBLISHED.

1890.

17,711. EDMUNDS. Distribution of electricity. (Price 11d.)

18,158. GRAY. Electric pressure indicator. (Price 8d.)

18,270. MUNRO. Electrical conduits. (Price 8d.)

19,239. BARTON. Electric switches. (Price 8d.)

19,486. BENNETT. Telephonic switching apparatus. (Price 8d.)

19,650. SIEMENS BROS. AND CO. (Siemens and Halske). Distributing electricity. (Price 8d.)

1891.

9,683. RAWLINS. Electric primary batteries. (Price 6d.)

12,046. SAHULKA. Electric motors. (Price 8d.)

15,597. TISHER (THOMPSON). Galvanic battery. Price 6d.

15,621. CURRIE. Secondary or storage battery. (Price 8d.)

15,645. GREENFIELD and KINTNER. Ceiling blocks and cut-outs for electric light circuits. (Price 8d.)

COMPANIES' MEETINGS & REPORTS.

West India and Panama Telegraph Company (Limited).

The twenty-ninth ordinary general meeting of the members of the West India and Panama Telegraph Company (Limited) was held at Winchester House, Old Broad-street, on Tuesday, "to receive the report of the Directors and the accounts for the six months ended June 30, 1891, to declare dividends, and to transact other business of the Company." Mr. C. W. Earle presided.

The SECRETARY (Mr. R. T. Brown) read the notice convening the meeting and the minutes of the last meeting; and the report of the Directors was taken as read.

The CHAIRMAN: The report deals with a period which I am afraid was not very prosperous to West Indian commerce. At any rate it was not nearly so good as in the corresponding period of 1890 it would appear to have been, judging from our traffics; and I do not think we can have a better barometer of the commercial doings of countries like the West Indies, where there is no great Stock Exchange speculation like there is in New York, and, fortunately, no revolutions as there have been in South America. I think that in such a country as that the traffic receipts form

Digitized by Google

a very good barometer and test of what business is doing. Before the appearance of the French cable in our territories took place, which was in the beginning of June, the decrease in comparison with the previous year amounted to 10 per cent., and I should presume that this decrease was owing to the bad sugar crop. Perhaps, Sir George Chambers will correct me if I am wrong on that point. The whole decrease in our receipts amounts for the half-year to £4,710. As a set-off against this loss, we have a saving of £1,800 in the expenses; and the balance of £22,773 is what we have to deal with, as compared with £25,681 in the corresponding period of the year before, making a net deficit altogether of £2,910. Well, gentlemen, as you see by the report we have placed £2,000 to the reserve fund, and we propose, with your sanction, to pay the dividends upon the Preference shares, and to pay one shilling per share, free of income tax, to the ordinary shareholders. Now, the set-off of £1,800 is attributable to the reduction in the cable repairs under Abstract C, of the accounts. We had the good fortune to have only seven interruptions to our cables as against 12 in the corresponding period of the previous year, and we spent in repairing these interruptions 44 knots against 72 in the former period. If it had not been for the larger cost of cable this year, the reduction in expenditure would have been very much more, but as you all probably know, iron and copper and certainly gutta-percha and wages, had a great rise a year ago; and the result of it was that our stock of cable, when it got out to the West Indies, cost some 40 per cent. more than it had done of late years. I do not intend to take up your time with any close analysis of the debit side of the revenue account. There is, in fact, very little to remark upon. Some items are larger than they were in the corresponding period of 1890 and some are rather less, but on the whole, there is a balance of £200 against us, and that is caused by the allowance of some small sums to various clerks—a matter which is likely to be set right the next time we present an account. I now turn to what you will doubtless think the most important part of our report, viz., that which treats of the competition that has appeared in our system. You have been informed from time to time both in our reports and in my remarks to you at our meetings, of the approach of this competitive cable. I think that the first time we had to apprise you of the possibility of the danger was in 1887, when the then Minister of Posts and Telegraphs in France brought in a Bill in the Chamber of Deputies to grant a guarantee of £40,000 a year to a line of cables between North and South America, touching the French Colonies of Guadeloupe, Martinique, and Cayenne on its way. Well, the Chamber of Deputies threw out the Bill—I suppose because they did not see what interest France as a nation had in a line connecting two foreign countries on the other side of the Atlantic. The project appeared then to drop, but in 1888 a French Company, which is not so formidable a competitor as it would have been with a guarantee of £40,000 a year, laid a cable from Cuba to Haiti, St. Domingo, Curaçoa, and Venezuela; and we announced in our report of April last year that the same Company had obtained the transfer to itself of the subsidy hitherto paid us by the Government of Martinique. We then were made aware that it was preparing to compete with us at Guadeloupe and Martinique, where we have been established for 20 years. As announced in the present report, this line was opened for traffic early in June last. We had no intimation of the tariff at which they intended to work; and as their rates on the Venezuela cables, which had been in operation for some time, were higher than the rates on our lines mile for mile, we did not suppose that they would adopt the ruinous policy of working at rates below those which we had found by long experience so inadequate. However, I suppose for some object of their own—probably to get the French subsidy—they opened at a tariff of 2s. a word below ours for Guadeloupe and Martinique; and we, deeming it expedient to prevent diversion of the traffic, and to put our own Colonies on as favourable terms as the French Colonies, made proportionate reductions at our more distant stations. The result has been what anybody acquainted with the effect of tariffs in countries like the West Indies would foresee, a considerable decrease in our revenue. But you must not attribute all the decrease our traffics are showing to the effect of competition. We have made a calculation of how much of the loss we are incurring is owing to the competition and how much to the natural loss of traffic; and it would appear that more than one-half of the loss we have sustained by the two is attributable to declining traffic, that we are sending fewer words at the lower tariff than at the higher. I therefore hope and trust it is a very exceptional position. It is difficult to imagine a less justifiable competition from the point of view of what is to be earned. We have proved by the experience of many years that there is not traffic enough in the West Indies to support one Company properly; and the appearance of another in the field, where the telegraphic service has always been carried on at less than cost price—for we have never been able to earn anything approaching to a fair return on the capital embarked—can only be disastrous to the new comers, costly to us, and in the long run disadvantageous to the public. Well, gentlemen, I suspect that our competitors are already beginning to find that West Indian Telegraphy is not a business in which to make fortunes. They now have two cables broken down; and, as far as I know, no means on the spot of repairing them, and I am inclined to guess that the short experience they have gained is somewhat discouraging. However that may be, we are in for a competition struggle. It is not one of our seeking, but has been forced upon us, and we must go through with it; because there is no other course open to us. We have tried and failed. We are better prepared for it than our adversaries; our lines are duplicated—they are dependant upon single cables; we have our ships and our establishments for the storing of cable for repairs—the French Company at present have none. By your wise provision and self-denial a fair reserve has been established to meet possible contingencies; and, although we must suffer in our revenue while the contest lasts, we hope that our losses, disappointing as they are just as we appeared to be entering into a more prosperous condition, will not continue to be so severe as the present traffic returns indicate. We have to-day had the traffic return for the last fortnight, which is much more favourable. It shows a loss, but, compared with the losses we have had recently to announce, it is very satisfactory. I am informed that the next year's crop of sugar promises well, and if that harvest is a good one we may return to at least the same volume of traffic as we carried last year. I have now only to ask you to continue to give us the confidence we have now enjoyed for 17 years, and to remember in our discussions to-day that it is not wise to hold a council of war with open doors, as these meetings unavoidably have to be held. I now propose:—

"*That the Directors' report and accounts to June 30th, 1891, submitted to this meeting, be and the same are hereby received and adopted; and that, as recommended by the Board, a payment of 6s. per share on the First Preference, 6s. per share on the Second Preference, and 1s. per share on the ordinary shares be and the same is hereby declared.*"

Mr. WILLIAM FORD: I beg to second the resolution, and, at the same time, I gladly avail myself of the opportunity of thanking you for the very cordial manner in which my re-election was voted at the last half-yearly meeting, when I was prostrated with a severe attack of influenza. Gentlemen, I can assure you that if prudence permitted, it would be a great satisfaction and relief to me to be enabled to place before you, as I have done on former occasions, my personal views as to the position and prospects of this Company; but concurring as I do in the views expressed by my honourable friend the Chairman, I feel that it would be exceedingly imprudent in me to say anything more than this, in the abstract—that I believe this Company was never in a better position to meet the adverse interests opposed to it, and I believe that we must in the long run succeed. I am not fond of using the language of Jingoism; but if I were I should say certainly that we have got the men in the able managers of submarine cables who sit at our Board, that we have got our repairing ships, and that in our reserve we have got the money too. The national sentiment, as I will call it, in which this French cable had its origin is all very well in its way, but national sentiment will not earn dividends on capital; and I am perfectly satisfied that this cable was as commercially unnecessary as I believe it will prove unprofitable to its owners. With these observations I beg to second the motion.

Sir GEORGE H. CHAMBERS said that it had not been his intention to offer any remarks, because he was quite alive to the circumstances referred to by the Chairman and by Mr. Ford. As, however, the Chairman had alluded to him by name, he had great pleasure in stating that what that gentleman had said was strictly accurate, and that the decline in their revenue might be attributed entirely to the bad weather in the West Indies, which caused the crops in many instances to be less than half what they had previously been. Therefore he entirely concurred with the Chairman that with the prospect now before them of perhaps more abundant crops than ever, they might see a return to the figures to which he had adverted. The accounts before them showed that the net revenue of the Company for the six months to June 30th was equal to paying a dividend of 3s. per share for the half-year upon their ordinary shares. He would have preferred, remembering the many years during which the ordinary shareholders were without a dividend, that instead of taking one-third of the net revenue for dividend and two-thirds for the reserve fund, the Board should have taken two-thirds for dividend and one-third for reserve, and he thought that this might safely have been done. Nevertheless, as they had competition to face, it was, perhaps, better that they should keep on the safe side. Probably there were some gentlemen present who knew that he was a warm advocate of a reserve fund, which had been found extremely valuable in the case of another Company with which he was connected, enabling that Company, as it did, to hold its ground while ruin befell its opponent. He therefore never objected to a moderate reserve fund. Sometimes competition was not altogether a loss. He knew some occasions where competition had increased the traffic, and he thought that that might very likely occur in their own case. He hoped that with the prospects they had in regard to the coming crops they would be able to receive from the Chairman an even more satisfactory account at their next meeting than, as he considered, had been made to them that day.

Mr. CHAMBERLAIN enquired how much the Company had lost by the reduction of the takings since the beginning of the present half-year?

The CHAIRMAN: The aggregate decrease for the four months of June, July, August, and September was £5,576; but, as I said before, more than half of that is attributable to the smallness of the number of the words telegraphed—the falling off in our trade.

Mr. THORP remarked that a previous speaker had alluded to the carrying over of such a large amount, and he himself thought that this was a very fair subject for comment. He did not object to putting £2,000 to the reserve fund; but why should they carry forward £5,200, when out of this amount they could easily pay another shilling a share dividend and carry forward £300?

The CHAIRMAN: Because we have very heavy repairs going on this half-year, and the traffic is, as I have said, very bad compared with what it was before. Unless we save something this half-year by carrying over a large sum, we may not be able to pay our Preference Dividends next half-year; and, as these dividends are cumulative, they would hang over the ordinary shares and make things as bad as they were before.

Mr. THORP, continuing, said that his point was that the money which had been earned in the past half-year belonged to the ordinary shareholders. It ought not to be paid in dividend to the First or Second Preference shareholders, who, no doubt, had the right to cumulative dividends. They had not the right, however, to retrospective dividends; and if the money now in hand was not paid to the ordinary shareholders, it would be absorbed by the Preference shareholders, who would thus be placed in a better position than that which they were entitled to hold. They had a very long "pull" of it if they had to wait for a half year, whereas the ordinary shareholders had to wait many years. He,

Digitized by Google

therefore, thought it was only fair that the earnings which had now been made should be paid to the ordinary shareholders, as they had the right to them.

Mr. WILLIS observed that for the half-year ended December, 1890, the Directors paid a dividend of 9d. per share, and carried forward £668, but nothing was added to the reserve fund. Now, however, it was proposed, after putting £2,000 to the reserve fund, to carry forward £5,255, while in his opinion the Directors might pay, on the same principle as in the previous half-year, 2s. 6d., and carry forward the same amount, or just about the same within £30. The ordinary shareholders had had, he believed, one dividend in 14 years at 9d., and he really thought that it was a very great hardship that they should be kept out of their dividend when the First and Second Preference shareholders had had their dividends in full. They might have had to wait, but they had been paid in full; and taking into consideration what the Chairman had said with respect to the abundant crops they were likely to have, he thought that at least 2s. a share dividend should be paid to them. The Directors would then be able to carry forward a very large sum, seeing that on the previous occasion only £668 was carried forward and a dividend of 9d. paid. He felt very strongly inclined to move a resolution to the effect that the dividend on the ordinary shares should be 2s., and that the balance then remaining should be carried forward.

Mr. W. GRIFFITH said that, as an ordinary shareholder, he rather sympathised with the remarks which had been made as to the dividend not being larger this year; but still, he thought that the policy of the Board was in this respect a sound one. If a larger dividend were paid and the receipts were to fall off, and if their cables were to break, they would have to appropriate a much larger proportion of the revenue to the repair of the cables. Although, therefore, they put the money by it was for the advantage of the Company at large—for the ordinary as well as for the Preference shareholder. The interest paid to the latter was limited, but it was a cumulative charge, and if once their reserve fund got into disorder and their cables were broken, as was the case a few years ago, the payment of a dividend on the ordinary shares would again be indefinitely postponed. He did not think that they were likely to be indefinitely postponed if they had a fair reserve fund. He was not in favour of increasing the reserve fund beyond what was necessary to ensure the safety of their cables, but the present was a somewhat critical time for them. Sir George Chambers has said that he hoped competition would increase their income, but unfortunately it had not done so hitherto; and he did not think that competition would be a benefit to them in time to come. Our West Indian Colonies differed very much from the Northern States, where great energy was shown. The trade of the West Indies was very stationary, and the Governments were very conservative as to free trade. They imposed very heavy taxes on all goods that were imported, and trade was to a great extent hampered by our own Government. If the West Indian Colonies could be persuaded to adopt a more liberal tariff towards English merchants they would benefit greatly. It must be remembered that the Company's system was a very complicated one. They supplied the telegraph wants of Danes, Spaniards, French, and others. Unfortunately, they had lost the French traffic to some extent, but; fortunately, on the other hand, the French traffic was only a small part of the traffic from the West Indies. From this circumstance he thought that they might draw some hope that when the good times of the harvest came their traffics would be increased, and that the ordinary shareholders would reap the proper reward for the very great patience which they had displayed.

The CHAIRMAN: We have not got a complete return of the traffic from the beginning of this half-year. There was an interruption to one of our lines, and we had to transmit the traffic by another way; and until we get the papers we shall not know what the returns exactly were. The returns we received were stated to be unreliable, and I will not pledge myself to any figure. You may, however, form a very good idea when I tell you that for June, July, August, and September, the aggregate decrease was £5,576.

Mr. CHAMBERLAIN said that before the Chairman replied he desired to make a few remarks. Several shareholders had spoken against the policy of the Board in adding to the reserve fund the sum proposed, and in carrying forward such a large amount; but he wished to say, as an ordinary shareholder—holding two or three times as much in ordinary shares as in First Preference shares—that he entirely approved this policy, and he thought it was to the interest of the ordinary shareholders quite as much as in that of the Preference shareholders, or more so. The reason he had asked for the information about the returns was that he had wanted to see how far they made the position of the First Preference shares secure without the reserve fund. He hoped that the position of the First Preference shares was secure, and that their returns would not fall off to such a serious extent as to prevent the payment of the Preference dividends. In any case, however, he would remind the ordinary shareholders that it was to their interest, as far as possible, to obtain a regular dividend, however small it might be, rather than a large amount one year or one half-year, and nothing at all for two or three half-years in succession. What was set aside by the Directors at the present time was in hand at all events, and though they did not divide it that day it would be divided hereafter. They would, therefore, not lose anything in the shape of dividend, and if they had to part with their shares they would gain by their improved market value. In addition to this the Chairman had said that it was not desirable to discuss too closely their position in view of the competition of the other Company. They were in active and very severe competition, and he thought it was most important that the Directors should be able to show the foreign Company that they were in a very strong position. The Board would be much better able to deal with this competition if they showed their rivals that they had the support of their shareholders, and that they had large funds at their disposal to make the position of the Company secure.

Sir GEORGE CHAMBERS said that the West India Colonies had had to bear the brunt of emancipation, the admission of slave-grown sugar, and to face the bounty-fed sugar from the Continent; and he thought that Colonies which had had to go through such difficulties deserved the sympathy and not the reproach of their fellow countrymen.

Mr. SAUNDERS said he thought that what the Directors proposed was not only judicious, but was also in the interest of the ordinary shareholders. It would be very bad for them if, by not looking after the reserves, the ordinary shareholders had to revert to their former position, with arrears of dividends on the Preference shares to be cleared off.

The CHAIRMAN: I can assure you that the question of how we were to deal with the balance at our disposal this year caused us very great anxiety; and we studied that question and debated it from every point of view. You must remember that we who sit at the Board know more of what is going on than we can tell you, or than any one else knows; and having regard to the heavy sums which we must pay for repairs and to the falling off in our traffic—which I hope is not going to be so serious as it was in the early part of the half-year—we came to the conclusion that it would be better to keep ourselves quite strong and to carry over a comparatively large sum to next half-year. I hope that our ordinary shareholder will not be the sufferer by this, and I do not see how he can, because if we fall into arrears with our First and Second Preference dividends, I am sure that the effect, the accumulating bad effect, on the ordinary shares is more serious than the loss of a dividend of 1s. a share. For 15 years there was the effect of a heavy weight of debt hanging over their shares, depreciating them, and doing them far more harm than going without a dividend.

Mr. WILLIS: Will you please answer the question why you paid 9d. before and carried over £600, while now you only pay 1s. and carry forward over £5,000?

A SHAREHOLDER: The explanation already given is quite satisfactory.

The CHAIRMAN: We cut our coat according to our cloth. He then put the resolution to the meeting in the usual way, and having declared it carried unanimously, stated that that concluded the business.

Mr. GRIFFITH proposed a vote of thanks to the Chairman and Directors for the conduct of the Company's affairs in the past half-year. They might, he said, differ a little as to policy; they might think that more might have been paid to the ordinary shareholders; but he thought they must have some confidence in the Directors for what they had done in the past. He might be permitted to remark, in reply to Sir George Chambers, that his sympathies for the West India Colonies were as great as those of that gentleman's. He, however, thought that the principle of free trade would be for their benefit. They were suffering now from the suicidal policy of the French Government as to bounties, but he hoped that that would not endanger their trade in other respects.

Mr. GREGORY seconded the motion, which was carried unanimously.

The CHAIRMAN: Gentlemen, we are very much obliged to you for your vote of thanks, and on behalf of my colleagues and myself I beg to thank you.

The proceedings then terminated.

Woodhouse and Rawson United (Limited).

The annual general meeting of the shareholders of this Company was held on the 13th inst. at the Cannon-street Hotel, under the presidency of Sir Rawson W. Rawson, K.C.M.G., C.B.

The SECRETARY having read the notice calling the meeting,

The CHAIRMAN said: Gentlemen, I have much pleasure in presenting you with an account of our stewardship during the past year—the second year of our existence. Considering the extraordinary financial crisis that has occurred during that year and the general commercial depression which ensued, we trust you will find the results of the Company's operations for this period eminently satisfactory. Deducting from both sides of the account the £16,000 brought forward from the previous year, you will find that the total earnings of the Company amounted to £89,000. Out of that we have provided for all our current expenses, and for what we consider a sufficient amount in reduction of the value of our patents. We have paid the interest due on our debentures, and have written off £10,500 for extraordinary expenses, some of which might fairly have been distributed over a further length of years; and we are left with a balance o £35,000 with which to meet our dividends of 15 per cent. on the ordinary shares and of 8 per cent. on the preference shares. These dividends will amount to £30,500. Consequently, having made a clear net profit of £35,000, we have a surplus of £4,600 applicable to such purposes as the shareholders may decide in agreement with the Directors. If we add to that the £10,000 of extraordinary expenses, our earnings during the year were £15,000 above our current expenses and dividends, without trenching upon the £16,000 brought forward from the previous year. The Directors hold, and we trust that you will hold, that in such an extraordinary year as that through which we have passed this result will be regarded as completely satisfactory, for it should be remembered that the character of the year peculiarly affected this Company, one branch of whose business is to avail itself of new inventions, to utilise the patents which it possesses, and to interest the public in new inventions connected with electricity. This, however, has been a year in which the public have not been disposed to enter upon new undertakings, and therefore we have had very little encouragement in this direction. We have had a number of proposals at different times, but we have not thought it right to accept them or to move in regard to them; and yet in spite of this we have made a clear net profit of £35,000. Passing to the balance-sheet, we have reduced the mortgages on freehold property by £3,000. The sundry creditors stand at £8,000 less. We have swept away the whole of the guarantee fund, which stood in the last balance-

Digitized by Google

sheet at £75,000. We have repaid the whole of that to Woodhouse and Rawson (Limited), according to the authority which you gave us at a previous meeting. You find inserted here for the first time the item of reserve fund, £25,000; and the pension fund of £1,065 is for the benefit of our *employés*. Turning to the credit side, the freehold premises show an increase of £12,000, which is caused by the new building and the improvement of the engine power at Cadby Hall, and also sundry improvements in the Kidsgrove property, which was taken over at the commencement of the year and necessitated certain outlay. The three items of plant, stock, and expenditure on contracts in hand are very heavy, and show a large increase; but the explanation of that is very simple. We only commenced our work last year. The United Company having acquired new works, having made a new organisation, and having extended the business, I may say, throughout the world—in Australia, South Africa, and other parts—necessarily had to make a large outlay on works, plant, supply stations, stock, installations, and contract work for the business in progress. In fact, what did we ask money for but to extend our business? The explanation of the increase in these items is simply that we have extended our operations—legitimate operations connected with our trading and manufacturing pursuits—and it is an evidence of the increase of our business. At the commencement of our operations it was advisable to advertise largely; and another important matter is that we have prepared, and are on the point of publishing, certainly the best catalogue—the most complete and the most exhaustive catalogue—of electrical and engineering apparatus and subjects of supply connected with electricity of any firm in the world. We are very proud of it, and it is calculated very much to improve the standing and credit of the Company, and to extend our business throughout the world. The consequence has been that in the past year—and perhaps in the present year also—there has been a large amount, but not an improper amount, expended upon advertising and printing. We have thought it right to spread the whole of the cost of this over the past year and the present year, instead of over four or five years. We think it better to meet, as far as possible, all our expenses as they arise; and as our earnings are sufficient to cover them, we have charged in this instance half of this expenditure to last year's revenue, and we intend to charge the other half to that of the present year. The next item is patents, patent rights, &c., on which there is an apparent increase of £10,000. This has not arisen from any material addition to the patents which we possess, but from the completion of the purchase of two of the Woodhouse and Rawson subsidiary companies. We have not added to the value of our patent and goodwill, except in connection with the completion of this original contract. The same remark applies to goodwill as to patents.

Mr. SAMUEL POPE, Q.C.: It is the same as before, *plus* the amount of the two new Companies taken in since last year.

The CHAIRMAN: We find in the first balance-sheet only £11,000 under the head of sundry investments, but you must take into account that below that there was invested a sum of £75,000 which was reserved to repay Woodhouse and Rawson (Limited). Our investments, therefore, in the first year's balance-sheet were £87,000, whereas that figure now is £119,000. You would probably like to know what these investments consist of; but it would be opposed to your interests and the practice of companies if I were to give you that information here. All I can say is that the valuation of these investments has been taken at the lowest and most reasonable figure; and, as far as we know, they are investments, not speculative, of the nature of which you have perfect cognisance. Last year investments which stood in our balance-sheet were parted with at a price above that which they figured for in our books; and we hope that by not throwing these investments on the market in an unreasonable manner we shall be equally successful. Any gentleman present, if he is acquainted with business, knows that it would be attended with most injurious consequences, not only to ourselves but to the companies concerned, if we were to come upon the market in an ill-advised manner. We shall, however, dispose, we hope next year, of these investments upon equally advantageous terms as we have done others. Our Managing Director authorises me to say that we have already disposed of some of these investments, and every one of them beyond the price shown in the balance-sheet. The debtors have increased, but, of course, they will increase; £30,000 of the amount is guaranteed. I will now go to the profit and loss account. In regard to the first item of salaries, my relation, our very able Managing Director, is a sufferer. The salaries in the first year were largely increased by his remuneration, which, as you know, or you ought to know at all events, depends upon the surplus of profits in the year. The consequence is that as the surplus this year is very small—that is to say, the surplus after paying all claims, including the dividends—his remuneration is very small; and that explains the decrease under the head of salaries. There is a large increase under the head of debenture interest. With respect to the writings-off from patent and patent rights, we have applied £4,156 to this purpose, acting upon this principle. We consider that if we write off one-fourteenth, the "life" of a patent being 14 years, this item will be gradually written off and will disappear. I am eminded that some foreign patents are not limited to 14 years, but English patents are. Last year we applied £7,400 to that purpose, but this year we have not applied so much, though the two amounts make up two-fourteenths in the two years. We have therefore written off £11,500 from our patents, and we shall go on writing off one-fourteenth every year. If it be objected that the patents which we possess do not all have a remaining duration of 14 years, the answer is this—that for some of our patents we have paid nothing, and they do not stand in our books as possessing any value, although some of them are very valuable. With reference to another class of our patents, the only charge that we create in connection with them is the charge for registering them. Placing this circumstance against the fact that all our patents have not a "life" of 14 years, we consider—and I hope you will consider—that to deduct every year one-fourteenth off our patents is a reasonable calculation, and will bring us at the end of the 14 years to a clear sheet. The next item is income tax for 1890 and 1891. The income-tax for 1891 is a legitimate charge against this year's account, but the other is in arrear. It ought to have been introduced into the charges of last year, but we did not know the amount, and there was a dispute between the officers of the Company and the Inland Revenue with reference to the amount for which the Company was liable, That was not settled until this year, and therefore the income-tax for two years is charged in the present account. The mortgage debentures redemption account is explained by the sum paid to the holders of debentures bearing 6 per cent. for the redemption of these 6 per cent. debentures, and the acceptance of debentures at 5½ per cent. The next item is preliminary expenses, and the explanation of that is that the expenses actually paid in connection with the formation of the Company—various charges which it is impossible to explain in detail—were not paid in the first year. This year it has been considered proper to write off the whole charge. As to the item of £2,000 for the Cadby Hall removal, part of that is the estimated cost of the removal of our business from the one block in which it formerly existed into the new block. It is partly cost of removal and partly the loss occasioned by the shifting of machinery and works and the impossibility of undertaking new work while on the point of removing. All these we consider are proper charges against the year, instead of distributing them, as we might have done, over a wider range. On the other side of the account the gross profit was not so large as that of last year, but it is impossible to be blind to the fact of the very different state of circumstances which existed last year as compared with the preceding year and the opportunities possessed by the Directors of making profits. The balance of interest is £3,000 more. The item of rent is derived from our West Kensington lease, which did not appear in our other balance-sheet. The item of "premium on shares, transfer fees, &c.," remains the same The profit and loss account shows a profit carried to the balance-sheet of £51,439. We propose to transfer £10,000 to reserve fund, and to carry forward to next account about £9,000. I trust you will find that that is a very satisfactory explanation of our working during the year. The Managing Director—prompted, I believe, by an excellent colleague—points out that this brings up our reserves, made in our two years' working, to £45,000.

A SHAREHOLDER: £35,000.

The MANAGING DIRECTOR (Mr. Frederick L. Rawson): £45,000. We carry forward nearly £9,000.

The CHAIRMAN: I shall not detain you much longer, but there are two or three points in the report to which I should like to refer. Before doing that, however, there is an important point that I should like to speak upon, as I feel a personal and great interest in it—that is, the refusal to us of a quotation on the Stock Exchange. Lord Aberdare promised this as far as he could promise, and I did the same; and in all my communications with the shareholders I have stated my belief—I have given the assurance—that, as far as I knew, there was nothing to prevent our having a quotation. I have had full justification for holding this view. Our papers, after sundry references and considerable delays required by the Stock Exchange, were pronounced to be in order. We had every reason to suppose that we should obtain a quotation, and that the only cause of the delay was the convenience of the Committee of the Stock Exchange, some time being required by them to understand and examine our papers, which were voluminous. Three weeks before the quotation was refused we had the most reasonable expectation, from parties of the highest position on the Stock Exchange, that the quotation would be granted; and the refusal took us entirely by surprise. We had not the least knowledge why the quotation was refused, for the Committee of the Stock Exchange is autocratic, and does not give its reasons. The only surmise that we can form is this—that until the old Woodhouse and Rawson (Limited) Companies are wound up the Stock Exchange will not give us a quotation. They have, however, granted a settlement. We are given to understand that after reasonable delay we may get a quotation if we apply again. I hope you will allow us to use our discretion as to the proper time for doing so. My own impression is that we should not apply for it until the Companies I have just mentioned are wound up and we stand upon our own legs. There are two or three points in the report to which I will now refer. A very great improvement has been made at the West Kensington Works by the erection of the new block of buildings there and the new engine-house. This will enable us to undertake a class of business which is likely to prove highly profitable. The source of our credit and profit is the manufacture of specialities. We aim at giving the public special apparatus of value and importance. We have been confined hitherto to that class of business; but this new block of business will enable us to undertake on a large scale the manufacture of mechanical articles—for instance, type-writers, and articles of that kind requiring great delicacy and suitable to our *employés*. We have a whole floor, and a very extensive floor, in that building where we can turn out many thousands of machines. We have another contract which we hope to commence upon in a few weeks; and we look to have a considerable extension, both of business and profit, on this new branch. With reference to the Kidsgrove property, you must remember that we only entered into possession of it at the beginning of last year. That was a business that required considerable improvements in many ways, and we anticipated that when we bought it; but we had to carry out, at a disadvantage in many respects, the works begun by the previous owners of this property. All that has passed away, and in the coming year we expect very different results from the working of the Union Foundry at Kidsgrove. In acquiring this foundry it must not be supposed that the Directors have plunged into the acquisition of these works simply to make new business. The object of our acquiring the Union Foundry was this—we possess the means of making all electrical apparatus of a small character—switches and a variety of things of that kind, but we had no works where we could manufacture on a large scale dynamos and engines peculiar to electrical purposes, and to introduce new inventions—specialities, as I call

Digitized by Google

them, such as are noticed in the report—hydraulic machinery, Mr. Bolton's electric cranes and winches, and things of that kind. That was our object in acquiring these works, and before we meet again I hope we shall be able to report a sound and profitable business in this respect. I may pass over the Cornbrook Telegraph Works. With regard to the supply department that is going on very satisfactorily. There was necessarily, during the year of which I am now treating, a large expenditure on that department to bring our stock up to the required amount. We have to maintain a large variety of different articles, which are required by our customers in all parts of the world. I do not believe that this outlay will be necessary in future years. As to our installation department, we have every reason to be satisfied. The business is largely increasing, and the character of our work is such as to do credit to us, and to secure confidence in us and our employers. A very important matter is that with respect to the Epstein accumulator. I hope you will consider it a proof of the discretion of the Board that out of the four inventions which we had under examination and testing, we accepted finally only one. We are not plunging into purchases or dealing with inventions which we are not convinced are likely to yield us profitable returns. We have had the Epstein accumulator under observation and testing for two years, and the result is as satisfactory as could be wished. We did not enter into any obligation with respect to this until we were satisfied that it was most efficient; that it opened a new field for traction purposes; that as regards efficiency and economy, it was superior to anything that existed, and also that we were perfectly secured in regard to it. We had the authority of four or five of the most eminent patent agents and leading counsel before we entered into an arrangement for the Epstein patent, in which we believe we have a most valuable property. The balance-sheet gives you an unexaggerated and fair statement of what we have done, and I may say that I have every reason to expect that our next year will be at least as good as the past year, or even better. He concluded by moving the adoption of the report and accounts.

Mr. PHILIP RAWSON, J.P., seconded the motion.

Mr. DIXON maintained that a larger amount ought to have been written off for depreciation of patents, which, he pointed out, were constantly being superseded by other inventions, and which therefore did not really have 14 years' "life." He did not think the 10 per cent. which was allowed last year was too much for the purpose. He objected to the £10,000, which was carried last year to goodwill account as reserve, being now "lumped" together with the rest of the reserve. Not a penny had been allowed for depreciation of goodwill. The Chairman had informed them that the investments were all right, but the shareholders had had no opportunity of judging for themselves whether that was so He had endeavoured to obtain information on the point, but had failed. He proposed an amendment adjourning the meeting for a fortnight to enable the Directors to consider these points, and whether the accounts could not be made more in accordance with what he called prudence.

Mr. BERBURY thought it would be better for the interests of the Company to carry forward more and to divide less.

Mr. W. GRIFFITH referred to the Auditors' certificate, and thought that the officials who had certified to the value of the stock investments, &c., should have their names put to the accounts in order that the shareholders might know who they were. He thought it a serious matter that their goodwill stood at £98,000 in the balance-sheet, which he presumed was the price paid in respect of it. He suggested that in future they should not extend their business so much by buying new patents and otherwise, and that they should get more established before pushing new business.

Mr. PEAKE said he could quite understand that it would be unwise to publish to the world the information respecting the nature of their investments; but he thought the shareholders would have much more confidence if they knew of what those investments consisted, and he thought they ought to receive information on this point if they applied at the offices.

Mr. S. S. BACON (Liverpool) said he had no idea of making any remark which should in any way disparage the valuable business of the Company, nor could he see how the shareholders would be benefited by refusing to pass the accounts at the present time. He perfectly agreed, however, with what had been said about the patents. He thought that more ought to have been written off the item, and he considered that it was "rather monstrous" on the part of the Directors in merging in the general reserve the £10,000 which was last year put to reserve for depreciation of goodwill. He also thought it was most unwise of the Directors to lock up the immense capital of the Company, as they appeared to have done according to the balance-sheet. They had locked up £93,000 in stock; and it looked to him, from the large amount of book debts, as if the Directors were rather financing their customers. Beyond this, there was the locking up of £119,000 in investments, of the nature of which the Directors did not inform the shareholders.

A SHAREHOLDER inquired whether he had understood that they were adding to the number of their patents from time to time at almost a nominal figure.

The MANAGING DIRECTOR, in reply, said that they had various foreign patents which did not expire in 14 years, and if they wanted to get the benefit of this longer term of years it was necessary to take out some of them before they took out the English patents. In this way they got an extended term. They had a large number of new patents continually taken out by their staff; these patents were the property of the Company, and they were shown in the balance-sheet at the cost of registration only. From time to time their patents thus became more valuable instead of less; but before long he hoped this item would be cleared off, and that they would have valuable patents standing in their balance-sheet at a nominal amount. They could not test the value of their goodwill in the first year, and therefore they put a large sum to special reserve. Now, however, the value of the goodwill had been proved. What he believed the Directors intended, and what his advice would be, was to write off the goodwill when the reserve fund amounted to a sufficiently large sum. They held the certificates of the officials who had certified to the values of the plant, &c.; and in regard to Auditors whom they had had to employ, his instructions had been to cut down the plant and stock as low as was possible. With reference to the new business, it could not be expected to pay in the very first year. The expenditure in connection with such business might have been spread over a series of years, but they had written off every penny. With reference to the investments, one of the shareholders had called on him the previous day to whom he had shown the list; and if the other gentleman who had spoken on this point would call at the offices he would be happy to show him the investments in the same way. Mr. Dixon could also see the investments.

A SHAREHOLDER: Why not show them to all the shareholders?

A SHAREHOLDER: There would be no certainty that the information might not be used against the Company.

The MANAGING DIRECTOR, continuing, stated that in the supply department it was necessary to keep a very large amount of stock. He thought it a good idea that the heads of the different departments should be made responsible for their stocks. The thing he was most anxious about was that the heads of the departments did not over-value their stock and plant; and as long as he was on the Board he thought the shareholders might rest assured with regard to this point. They were only on the eve of what they believed to be an immense extension of electrical work, and in order to be in the van and take part in this they must be able to supply largely all sorts of things.

The CHAIRMAN then put the amendment, which was lost by an overwhelming majority, only four hands being held up in its favour; and subsequently the original motion was carried.

Resolutions were afterwards passed declaring the dividends recommended, and re-electing the retiring Directors and Auditors.

On the motion of Mr. BACON, a vote of thanks was passed to the Chairman; and the proceedings then terminated.

Blackpool Electric Tramway Company (Limited).

The following is the report of the Directors for the year ending 31st October, 1891, to be presented to the shareholders at the seventh annual general meeting, to be held at the Victoria Schools, Tyldesley-road, Blackpool, to-morrow (Saturday), at 3 p.m.:—

The revenue account shows a balance in hand for the year of £3,049 2s. 6½d. Adding to this £184 17s. 7½d. from last year makes an available amount of £3,234 0s. 2d., of which the Directors recommend the following disposal:—

	£	s.	d.
Dividend of 7½ per cent. on the called-up share capital, free of tax	1,501	17	6
Depreciation and reserve fund	1,500	0	0
Balance to next year's account	232	2	8
	£3,234	0	2

The depreciation and reserve fund, with the addition of £1,500 as above recommended, will be £6,069 4s. 8d. The number of passengers carried this year was 933,652. The number of miles run during the year was about 98,000.

The retiring Directors are Messrs. Horsfall, Bickerstaffe, and Broadbent, who are eligible for re-election. Mr. Broadbent's services as Managing Director have been secured again for the coming year.

The transfer books of the Company will be closed from the 12th to the 21st November, inclusively.

Swan United Electric Light Company (Limited).

The following is the ninth annual report of the Directors of this Company, to be presented at the ordinary general meeting to be held at the Cannon-street Hotel, E.C., on Tuesday, the 24th inst., at 12 noon:—

The accounts are for the year ended September 30, 1891. After paying all current charges, and making due allowance for depreciation, there is a credit balance of £47,490. 11s. 2d. The Directors recommend that out of this balance a dividend of 11 per cent. for the year be declared; an interim dividend at the rate of 6 per cent. per annum, amounting to £11,104. 0s. 5d., has already been paid in respect to the first half of the year; the balance of the 11 per cent. for the entire year to be distributed in accordance with Clause 77 of the Articles of Association, and to be payable on December 1, 1891. This will absorb £28,376. 6s. 11d., and leave £8,010. 3s. 10d. to be carried forward.

The decision of the Supreme Court at Leipsic, in the patent cases which the Allgemeine Electricitäts Gesellschaft brought against the Company and their agents, has been given in favour of the Company. The Directors are now engaged in the consideration of the best way to take advantage of the favourable position thus created in Germany. The Compagnie Générale des Lampes Incandescentes in Paris have been in litigation as to their patents throughout the year. The experts to whom the Court referred the case have not yet rendered their report to the Judges, and until this is completed the Court cannot adjudicate on the case. The Compagnie Générale does a considerable amount of business, but competition is very keen on the Continent, and the selling price of the lamps is much reduced.

The Director who retires by rotation is Mr. J. W. Swan, who being eligible will offer himself for re-election. Messrs. Welton, Jones and Co., the Auditors, will also retire, and will offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

CENTRAL AMERICAN MINT (LIMITED).—This Company has been registered by Hays, Schmettan and Co., 31, Abchurch-lane, E.C., with a capital of £125,000, in £10 shares. Objects: To carry into effect an agreement made November 6th between Wm. Elmore of the one part and A. Stevens, on behalf of this Company, of the other part, for the purchase of a concession granted by the Republic of Salvador for the purpose of establishing a mint and to carry on in all their respective branches the businesses of coin and metal manufacturers, engineers, boiler-makers, wire-drawers, metal workers, &c.

DALZIEL'S NEWS AGENCY OF AMERICA (LIMITED).—This Company was registered on November 14, 1891, with a capital of £100,000 in £10 shares, by Messrs. Burton, Yeates and Hart, solicitors, 23, Surrey-street, W.C. The objects are: To enter into an agreement with Dalziel's Cable News Agency (Limited) for the acquisition of such part of their business as is now carried on in the United States of America, to carry on within the limits of the United States, but not elsewhere, the business of an agency for the receipt and supply of news and information of all kinds, and to carry on the business of advertising agents, newspaper proprietors, printers, publishers, newsagents, and stationers, and of a telephone, telegraph, and electric light, heat and power supply, and pneumatic despatch company, in all or any of its branches. The number of Directors is not to be less than two or more than seven, the first being D. Dalziel (Managing Director), W. C. Hallett, H. F. Jackson, and H. King. Qualification of Director, £100.

IMPROVED GALVANIZING COMPANY (LIMITED).—This Company has been registered with a capital of £75,000, in 2,500 £10 preference shares, 4,950 £10 ordinary shares, and 500 £1 founders' shares. To carry on in the United Kingdom or elsewhere the business of manufacturers of iron, steel and other metals, whether coated with lead or otherwise, and of iron-founders generally, and also to acquire any patents, patent rights, &c., in relation to the above objects.

ISLE OF WIGHT ELECTRIC LIGHTING COMPANY (LIMITED).—This Company was registered on November 12, 1891, with a capital of £1,000 in £1 shares, by Messrs. Deacon and Co., 4, St. Mary-axe, London, E.C. The objects are:—To carry on business as electricians, mechanical and electrical engineers, workers and dealers in electricity, motive power and light, and to carry on the business of manufacturers of and dealers in machines, lamps, and other appliances for supplying light and power by means of electricity. The number of Directors is not to be less than two nor more than five, the first to be appointed by the subscribers to the Memorandum and Articles of Association.

NEW JERSEY IRON AND STEEL COMPANY (LIMITED).—This Company has been formed to acquire the old-established businesses of the New Jersey Steel and Iron Company, the Trenton Iron Company and Wire Mills, the Durham Ironworks, the Passaic Rolling Mills, and the Warren Iron Company. It has a capital of £680,000. The Duke of Marlborough is the Chairman of the London Board.

NEW MOTOR SYNDICATE (LIMITED).—This Company was registered on November 11, 1891, with a capital of £5,000 shares in £10 shares, by Messrs. Bedford and Co., 6 and 7, Great Tower-street, E.C. It purposes to adopt and carry into effect an agreement between T. C. Hersey and W. M. Knight, and dated August 12, 1891, and to acquire and develop certain patents, further particulars of which are not given.

RAILWAY ELECTRICAL FOG SIGNAL SYNDICATE (LIMITED).—This Company was registered on November 12, 1891, with a capital of £25,000, in £1 shares, by S. G. Warner, 6, Quality-court, Chancery-lane, W.C. The objects are:—To carry into effect an agreement dated October 7, 1891, made between W. Andrews of the one part and J. Press, jun., of the other part, for the purchase of the interest of W. Andrews in certain patents, Nos. 18,747 of 1889 and 14,181 of 1890, to carry on business as electrical engineers and contractors, to carry on the business of manufacturers of and dealers in electrical apparatus, and also the business of an electric light company in all its branches. The subscribers are:—A. Moore and J. Lewin, of Netherfield, Notts; W. Langsdale and S. P. Derbyshire of Nottingham; M. Gregory, of Bridgford, near Nottingham; G. Tutin, of Beeston; and F. H. Bedells, of Nottingham. The first Directors are to be elected by the subscribers. Qualification, £250. Remuneration, £500 per annum, divided between them. Solicitor, Arthur T. Ashwell, Nottingham.

REALIZATION LAND COMPANY (LIMITED).—This Company was registered on the 14th November, 1891, with a capital of £2,000 in £1 shares, to acquire and develop land, and to erect, maintain, and carry on waterworks, gas works, electric light, heat, and power, supply works, telephone works, &c. Registered by the solicitors, Messrs. Terrell, Atkinson and Winstanley, 33, Gracechurch-street, London, E.C.

SOUTH NORMANTON, BLACKWELL, AND HUCKNALL-UNDER-HUTHWAITE GAS COMPANY (LIMITED).—This Company was registered on 12th November, 1891, with a capital of £15,000 in £5 shares, by Jordan and Sons, 120, Chancery-lane, W.C. The objects are to light with gas, electricity, or other illuminating means, the towns of South Normanton and Blackwell in the county of Derby, and of Hucknall-under-Huthwaite, Notts.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The statutory return of the above Company, made up to October 29, 1891, was filed on November 12th. The Company was registered on July 11, 1891, with a capital of £800,000, divided into 40,000 ordinary and 40,000 preference shares of £10 each; and the first ordinary general meeting of its members was held at Winchester House, Old Broad-street, E.C., on October 15, 1891. 30,152 of the ordinary shares have been taken up, and upon 1,500 the full amount has been called and paid, while upon the remaining 28,652 ordinary shares £4 per share has been called and paid, the calls paid amounting in all to £129,608. The balance of the ordinary and the preference shares are at present unissued. Among the shareholders are Mr. T. Apfel (475 shares), C. Barclay, Lord Claud Hamilton, and J. B. Braithwaite (500 between them). The Brush Electrical Engineering Company, Limited (2,575), H. L. Bischofstein (1,000), Hon. Alan Charteris (100), R. Crawley (370), Baron Emile d'Eichthal (200), Earl of Dysart (168), T. A. Denny (1,000), Lord Nathan M. Rothschild (5,000), Earl of Suffolk and Berkshire (100), Sir David L. Salomons (200), Eustace Smith (500), P. G. B. Westmacott (500), Countess of Yarborough (400), Electric and General Investment Company, Limited (1,000), Laing, Wharton and Down Construction Syndicate, Limited (52), Colonel B. H. Martindale and Sir David Salomons, jointly (1,500), and Colonel B. H. Martindale (100). Registered offices: 1 and 2, Great Winchester-street, London, E.C.

CITY OF WATERFORD ELECTRIC SUPPLY COMPANY (LIMITED).—The first registered office of the above-named Company, which was registered on July 1st last with a capital of £1,000, in £5 shares, is situate at 11, Queen Victoria-street, London, E.C. (Filed on November 12, 1891.)

EAST LONDON ELECTRIC SUPPLY COMPANY (LIMITED).—The first registered office of the above-named Company, which was registered on July 1st last, with a capital of £1,000, in £5 shares, is situate at 11, Queen Victoria-street, E.C. (Filed November 12th.)

ELECTRICAL ASSETS PURCHASE COMPANY (LIMITED).—An agreement, dated November 5, 1891, between the Liepmann Carbon Company (Limited) of the one part and this Company of the other part, states that whereas by an agreement dated July 13, 1891, the Liepmann Company agreed to sell, and C. E. H. Hoskins, on behalf of this Company, agreed to buy, certain premises for the consideration of 500 shares of £1 each fully paid in the Assets Company; and whereas that agreement was ratified by the Company in general meeting on November 2nd. The 500 shares, numbered 1 to 500 inclusive, are to be allotted to the Liepmann Company or its nominees. The above Company was registered on July 28th last, with a capital of £1,000 in £1 shares, to purchase the whole of the assets and effects of the Liepmann Carbon Company (Limited), including its British and foreign patents for "Improvements in the manufacture of carbon for electric lighting." Registered office: Eastcheap-buildings, 19, Eastcheap, E.C.

ST. JOHN'S, HAMPSTEAD, ELECTRIC SUPPLY COMPANY (LIMITED).—The first registered office of this Company, which was registered on July 1, 1891, with a capital of £1,000, in £5 shares, is situate at 11, Queen Victoria-street, E.C. (Filed November 12, 1891.)

WYNDHAM ELECTRIC LIGHT COMPANY (LIMITED).—The statutory return of the above-named Company, made up to November 2, 1891, was filed on the 10th following. The Company was registered on July 6, 1891, with a capital of £1,500, in £1 shares, to purchase certain plant necessary for electric lighting, for W. Williams, of Treherbert, Glamorgan, and to light the village of Blaenrhondda by electricity. 585 shares have been taken up, of which 100 were issued as fully paid. Upon the remaining 485 shares 15s. per share has been called and £200 paid, including £19. 10s. paid in advance of calls, leaving £183. 5s. unpaid. Registered office: Old Bank-chambers, Market-square, Pontypridd, Glamorgan.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts of this Company for the week ended November 16th amounted to £819; aggregate receipts for half-year to date, £14,365.

ECONOMIC GOLD EXTRACTION COMPANY (LIMITED).—The Directors of this Company have issued a circular announcing that the syndicate alluded to at the last general meeting as being formed for the working of their amalgamators in South Africa is now fully organised, and that there seems to be a likelihood of a considerable demand for the machines made by the Company. It is also anticipated that the Company will shortly be able to deal with large quantities of tailings, which may be profitably treated by the Company's process.

MORECAMBE ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The first statutory meeting of the shareholders of this Company was held on Monday evening, at the offices, Morecambe. Mr. G. R. Snowden presided. The secretary read a statement of the society's affairs, which was approved; and the Company's engineer attended with plan showing the position of central station and the main cables to be laid for supply. The provisional Directors were unanimously re-elected, with power to add to their number. The appointment of Mr. J. Duff as auditor was confirmed.

ORIENTAL GAS COMPANY (LIMITED).—At the meeting of this Company at the London offices on Wednesday, the Chairman, referring to the electric light, said that it had not at present obtained much of a footing in Calcutta. The Hooghly Bridge had been lighted with electricity, but it had not been a great success. Although they were constantly threatened with the production of electric light, he thought, in the face of an experience such as that to which he had alluded, they might be perfectly easy that for the present it would not materially interfere with their revenue.

REUTER'S TELEGRAM COMPANY (LIMITED).—A call of £2 per share on £3,500 new £8 shares is due to-day (Friday).

Digitized by Google

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LTD.).—The traffic receipts of this Company for the half-month to November 15th were £2,309 as compared with £2,602 in the corresponding period of last year, and show a decrease of £293.

WOODHOUSE AND RAWSON UNITED (LIMITED).—This Company are again applying to the public for further capital, and advertisements have appeared this week inviting subscription to 10,000 ordinary shares of £5 each (being the balance of 60,000 shares), upon which it is proposed to call up not more than £2. 10s. per share, and for 13,000 Seven per Cent. preference shares of £5 each, the latter being entitled to 7 per cent. preferential cumulative dividend per annum, together with 1 per cent. in every year in which the ordinary shares have received 10 per cent. dividend or upwards; also for 50,000 Five and a-Half per Cent. 1891 Debenture Stock, this being the balance of a total issue of £200,000, of which £65,500 is reserved for the payment off of a like amount of Six per Cent. Debentures outstanding; on this latter amount being paid off the Debenture Stock now issued becomes a first charge upon the entire undertaking. The time for sending in applications was up to and including yesterday (Thursday), and should this issue be taken up, the paid-up capital of this Company will amount to the large sum of £511,410, £146,410 of which ranks for a premium of 15 per cent. per annum (after the payment of 6 per cent. interest on the debentures, and 8 per cent. on the preference shares) for three years to July 1, 1892. The price of issue for the amounts now asked for is 5 per cent. per share premium on the ordinary shares, and the preference and debenture stock at par. From June, 1889, to June, 1891, the Company have duly paid 15 per cent. per annum on the ordinary shares, and the 8 per cent. per annum on the preference shares. We think that the balance-sheet issued by this Company would be more complete if fuller particulars were given as to the amount of plant and materials supplied to its numerous agents and the relation this amount bears to the sales effected by the various agencies.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 706.—Vol. XXVIII. FRIDAY, NOVEMBER 27, 1891. PRICE FOURPENCE. *Annual Subscription (U. K.), 19/6.*

NOTES.

The meeting at the Mansion House on Wednesday last ought to prove of some use in giving the Electrical Exhibition at the Crystal Palace a good start. An imposing Honorary Council of Advice has been got together, by which we mean that their names are all in print. A few of them turned up at the meeting, where a fair representation of the scientific and the commercial interests was also to be found. A report was read which referred to "Electric Force," "The Infant Electra," &c., and alluded too briefly to the Exhibition which was held at the Crystal Palace in 1881. The Lord Mayor, in a speech which followed the reading of the report, was apparently unaware that a successful and useful Exhibition had already been held at Sydenham. He naturally complained about the dawdling way in which the City lighting is proceeding. Mr. Preece followed with his well-known plea that, if looked upon in the proper way, electric lighting is as cheap as gas. He alluded to so-called "international" Exhibitions, and remarked that the idea was dropping out of fashion, that "the forthcoming Exhibition would be national, and English engineers would have an opportunity of making comparisons without being affected by prohibitive tariffs." Since no Protectionist country can with any sense of decency hold an "international" Exhibition, the idea of *national* Exhibitions is well worthy of consideration. Those who wanted to know how German engineers carry out their work had only to go to Frankfort to see a thorough display, and any who want to see American machinery will never have a better opportunity than that which will be offered by the Chicago Exhibition. Mr. Preece suggested that an important application might be expected in the direction of the development of heat, which is now often produced by very objectionable methods. The Duke of Marlborough followed Mr. Preece with a rather long account of the lighting of the City, and endeavoured to make excuses for the delay. The Crystal Palace Company may be very thankful that the trade have consented to support the Show. If a short Act were passed permitting Exhibitions to be held only in Leap Year, there would be some chance that they would be worth visiting. A ten-year period, as suggested and commenced in 1851, would be better still. May we never have another this century!

There seemed to be some doubt at the Mansion House meeting whether awards or prizes would be offered. It is to be hoped that the farce of jury inspection and the solemn adjudication of utterly worthless medals will be dropped. It is true a dozen well-known men have been entrapped into acting as a "committee of experts," and that a committee of experts is an admirable idea. You have, all in working order, machines and apparatus, which are, at other times, either employed on public service or are in the workshops; and there is a lingering feeling that some wonderfully complete test of the efficiency of dynamo, lamp, motor, or transformer may at last be made without bias. There is, however, but little mystery now about these matters, and an Exhibition is one of the worst places for carrying out a test. Looking back on other Exhibitions, we can only recall the arc-lamp tests at Philadelphia, and Prof. Kittler's glow-lamp tests at Munich; there have been other investigations, but they have long passed into oblivion. Nothing, indeed, would be more likely to make the forthcoming Exhibition a prominent landmark in the history of electrical engineering than the properly-directed labours of a well-chosen committee of experts. It seems to be a splendid opportunity for doing something, but we regret that we cannot say what. A good suggestion or two appears to be urgently wanted. There is one difficulty in the way, probably the difficulty that has always proved the obstacle in similar cases—namely, such that good men as are fortunately to be found upon the present Committee are fully engaged, and have no time for exhaustive tests.

We have on several occasions referred to the remarkable work of Prof. Minchin in connection with the sensitiveness of impulsion cells to the action of light; and from a short article we publish this week it will be seen that some of these cells are in many ways well adapted to detect the presence of electric oscillations. Many of them are marvellously sensitive, one described in this issue being capable of distinguishing between the sounds uttered in pronouncing different letters of the alphabet. When used for the purpose of detecting electromagnetic disturbances, they act merely as relays, and in this respect have an advantage over the spark micrometer of Hertz, in which the energy of the indicating spark has to be withdrawn from the oscillations under test. While, however, Prof. Minchin may possibly be correct in assuming that the impulsion cell plays the same part as that of a Hertz resonator, his experiments do not amount to any proof. The resonator of Hertz is remarkable, not so much on account of its extreme delicacy, as for the fact that it responds merely to the alterations in the strength of the magnetic field in

Digitized by Google

which it is placed; and the proof of this is afforded by its power of detecting nodes and internodes caused by the interference of the superposed oscillations. Not until the impulsion cells show a similar power can they be said to be capable of playing the part of HERTZ resonators, and even then the great care needed in handling them will prevent their use.

IN a recent letter to the *Western Daily Mercury*, Mr. C. H. RADFORD complains that the Plymouth district might now be enjoying an electric supply were it not for Clause 2 of the Electric Lighting Act of 1888. By this clause it is enacted that where any "undertakers" are authorised by Provisional Order or special Act to supply electricity within an area, any Local Authority within whose jurisdiction such area or any part thereof is situated may require the "undertakers" to sell at the end of the period specified in their authorisation, and the "undertakers" are thereupon obliged to sell, so much of their undertaking as is within such jurisdiction. Hence, although by the Act of 1882 no part of an area of supply need necessarily be comprised within the district of a Local Authority applying for a Provisional Order, a Local Authority can only exercise its compulsory purchase powers upon just so much of an electric-light supply system as comes within its borders.

"GREATER" Plymouth, it seems, possesses the privilege of being ruled over by no less than three distinct municipalities, so that the electric-light undertaking promoted by Mr. RADFORD could only obtain an Order covering the whole district on the condition that a central station was erected within the jurisdiction of each authority, since none of them wished to run the risk of having to purchase so many miles of unattached mains. Under these circumstances it was found impossible to proceed with the scheme. It may be remarked in passing that the London Electric Supply Corporation, although it has powers within the areas of some thirteen local bodies, has its generating station seven miles away from the richest districts supplied. Later on this fact may prove anything but an advantage. The Vestries may buy up the competing companies cheap and run their undertakings against the Deptford colossus. It is also within the bounds of possibility that the Deptford Local Authority, in a moment of public-spirited enterprise, might demand to have just so much of the undertaking as concerns it. On the other hand, should London ever be governed by one single municipality the relative position of affairs with regard to compulsory purchase would be reversed.

THE preliminaries of the attack on the LANE-FOX distribution patent are being arranged, and on Saturday last a motion on appeal from chambers for leave to amend interrogatories or something of that sort came before Mr. Justice ROMER. These preparatory preambulations are generally very dull, but there was a flash of "legal 'intelligence'" when a learned counsel began to instruct the Judge as to the use of mains. The Kensington and Knightsbridge Company use copper mains, but our readers may like to know how they are used. The current is generated in the supply station and is led by these mains to the lamps. "There it is partially consumed, but some comes back again by the conductor." This is really very interesting; we wonder what they do with this refuse waste current. Mr. PEMBER once said that the electric tramway companies made a cesspool of the earth; do the Kensington Company use these useless dregs of current that trickle back, "partially consumed" and scalded perhaps by the lamps, to flush the drains? So well managed a Company would not adulterate its freshly-generated current with such stuff.

Lambeth Vestry.—At the last meeting of this Vestry it was decided to apply for a Provisional Order.

Harwich.—At a meeting of the Town Council last week it was decided that the application for a Provisional Order should be persevered with.

Cable Extensions.—A duplicate cable, between Trinidad and Demerara, has been laid for the West India and Panama Telegraph Company.

Fareham.—Notice has been given by the Fareham Electric Light Company of their intention to apply for a Provisional Order for the supply of electricity for public and private purposes.

Halifax.—At a special meeting of the Town Council last week it was decided to apply for a Provisional Order to authorise the Corporation to supply electricity for public and private purposes.

Royal Society.—The following Paper was down for reading yesterday before the Royal Society:—"On the Electromotive Phenomena of the Mammalian Heart," by W. M. Bayliss and Dr. E. H. Starling.

Institution of Electrical Engineers.—On Friday, November 20th, a Paper was read before the students of the Institution on "Lightning Conductors and Guards," by Messrs. H. C. Haycraft and C. Minshall.

Proposed Extension of the City and South London Railway. Among the Parliamentary notices published in the *Gazette* is one on the part of the City and South London Electric Railway, to extend their system to Islington.

"L'Industrie Electrique."—It is announced by the *Bulletin International de l'Electricité* that a paper with the above title will probably shortly be started, under the editorship of M. Hospitalier, who will be assisted by the old *Electricien* staff.

The Thomson Meter.—The following figures are given of the number of Thomson meters manufactured:—On November 2, 1887, 680 meters; on the same date 1888, 2,680; 1889, 4,860; 1890, 10,000; and on November 2, 1891, 20,000 meters.

The Censorship of Telegrams in Brazil.—The Western and Brazilian Telegraph Company have received information that the Fiscals have been removed from all the offices in Brazil, and that there are now no restrictions on telegrams to and from that country.

Interurban Telephony in Holland.—The Dutch interurban telephone system will receive a considerable extension during the present month, when much more rapid communication than at present will be established between Amsterdam, Rotterdam, Utrecht, Haarlem, and other centres.

Pontresina.—The inhabitants of Pontresina recently formed themselves into a joint-stock company for the purpose of obtaining the electric light. Pontresina enjoys the advantage of possessing a 430ft. waterfall, so that some 500 H.P. is obtainable from a moderate supply of water.

Central London Railway.—At the last meeting of the Hammersmith Vestry the Works Committee reported that they had received an intimation from Messrs. John Aird and Son of their

Digitized by Google

intention to sink certain trial borings in Uxbridge-road and Caxton-road, as a preliminary to the construction of the Central London Railway.

Paris Municipal Central Station.—Last week one of the pavilions at the "Halles" was suddenly plunged in darkness, owing to the breaking of a steam-pipe. Within an hour, however, the damage was made good and the light again switched on.

Direct Spanish Telegraph Company.—During the temporary interruption of the Direct Spanish Falmouth-Bilbao cable, arrangements have been made by which telegrams from Bilbao, Madrid, and all places in Spain, can, during the interruption, be promptly forwarded by the Eastern Telegraph Company's route.

Electrical Standardising, Testing, and Training Institution.—The management of this Institution announce that they award a Faraday scholarship of the value of 80 guineas a year, and a Maxwell scholarship of the value of 50 guineas a year, both tenable for two years. Entrance exhibitions, ranging from 20 to 40 guineas a year, may be awarded by the Council to unsuccessful competitors. The next examination commences on January 6, 1892.

The Blackpool Electric Tramway.—In our last issue we made some remarks with regard to the favourable showing of the electrical plant at Blackpool. The plant in question was supplied by the Electric Construction Corporation; and we learn on good authority that after working about six years the dynamos (equal to 50,000 watts) and the motors on the ten cars seem as efficient as when first laid down, and have given every satisfaction to the users.

Proposed Electrical Railway from Finsbury Park to the City.—Parliamentary notice has been given of intention to promote a Bill in the next Session of Parliament for powers to construct an electrical underground railway, commencing by a junction with the Great Northern Railway at Finsbury Park and terminating in the City about the centre of Finsbury-pavement. Powers will also be sought to run into and use the Finsbury Park Station of the Great Northern Railway Company.

Hove.—The Electric Light Committee of the Hove Commissioners report that, in answer to their advertisement inviting tenders for the supply of electricity, communications have been received from several companies, including the Brighton and Hove Electric Lighting Company, and Messrs. Crompton and Co. The committee recommend the Commissioners to enter into negotiations with Messrs. Crompton, as that firm alone has accepted in its entirety the scheme adopted by the Commissioners. The committee also recommend that the services of an electrical engineer be obtained.

The Chicago Exhibition.—The following list has been issued of the nations and colonies who intend to participate in the Exhibition, with the amounts of the appropriations officially announced:—Great Britain, £25,000; British Guiana, £3,000; British Honduras, £1,400; Cape Colony, £2,000; Trinidad, £2,000; Guatemala, £24,000; Honduras, £4,000; Argentine Republic, £20,000; Austria-Hungary, £33,600; Bolivia, £20,000; Brazil, £110,000; Chili, £20,000; Columbia, £20,000; Costa Rica, £10,000; Danish West Indies, £2,000; Ecuador, £25,000; France, £80,000; Germany, £50,000; Japan, £100,000; Mexico, £150,000; Nicaragua, £4,000; Peru, £20,000; Salvador, £6,000; Cuba, £5,000.

Sir William Thomson.—Some months ago, at a private meeting of Glasgow gentlemen, it was agreed to ask Sir William Thomson to sit for his portrait (in order that it should be presented to the University of Glasgow) as a mark of the respect in which he is held, in recognition of his invaluable contributions to science. It was at the same time determined that a replica should be presented to Lady Thomson. Mr. Herkomer was entrusted with the work, and the portraits have now been delivered. It has been arranged that the presentation shall be made by Mr. A. J. Balfour, who was an original subscriber, and is an old friend of Sir William Thomson's, on the occasion of his visit to the city for the purpose of delivering his rectorial address. Principal Caird will acknowledge the presentation on behalf of the University. The ceremony will take place in the Merchants' Hall to-day, at 12 o'clock.

Tiverton.—In connection with the electric lighting of the town, Mr. J. Siddalls, the borough surveyor, has presented a report, in which he briefly reviews the general question of town lighting throughout the country. Mr. Siddalls sums up in favour of the high-pressure alternating-current system. The report includes a comparison of the cost of the electric light and gas. Mr. Siddalls recommends the Town Council not to undertake the lighting themselves, but to advertise for offers from firms willing to take over the Provisional Order for a specified term, or, with the assistance of the Council, to establish a local company, to whom the powers of the Provisional Order could be transferred. Accompanying the report is a table, giving some particulars of the various municipal installations throughout the country. At the last meeting of the Town Council this report was presented and the recommendations for advertising for tenders was adopted.

Liverpool.—The Liverpool Electric Supply Company are about to make application to the Board of Trade for an alteration in the terms of their Provisional Orders. At present the more central portion of the city is included in an Order granted in 1889, one of the terms of which is that the Corporation shall be at liberty to purchase the undertaking at the expiration of 21 years, instead of at the end of the customary period of 42 years. The remaining portion of the city in which the Company have authority to supply is included in their 1891 Order. In the case of the latter Order the Corporation did not insist upon any alteration of the statutory purchase clause. The Company, under their sliding scale, now charge a maximum rate of 1s. per unit, and, having regard to the 21-year period in the 1889 Order, it is impossible for them at present to reduce this rate. The Order for which application is now being made places both areas under the same conditions as regards purchase, and reduces the maximum charge for electricity to 8d. per unit.

The Christiania Central Station.—As our readers are aware, the tenders for the central electric station in Christiania have been in for some time, and the decision will shortly be made known. It may be interesting to repeat the names (see *The Electrician* October 23rd) of the twenty firms who have sent in tenders, either for the whole of the installation or for parts. They are:—The Edison General Electric Company (New York), Crompton and Co., Siemens Bros. and Co., The Electric Construction Corporation, Callender's Bitumen Telegraph and Waterproof Company (for cables only), Siemens and Halske, Schuckert and Co., Thomson-Houston International Electric Company (Hamburg), Helios Actien Gesellschaft (Ehrenfeld-Cologne), Düsseldorfer-Ratinger Röhren-Kesselfabrik, Ratingen (for boilers only), Compagnie Continentale Edison (Paris), Mather and Platt (for dynamos, &c.), A. L. Thune (Christiania) (boilers—Babcock-Wilcox), Göhrig and Leuch's Kesselfabrik (Darmstadt) (boilers), L. and C. Steinmüller Röhren Dampf-Kesselfabrik, Gummersbach (boilers), O. L. Kummer and Co. (Niedersedlitz), Sharp and Kent, Woodhouse and Rawson United, J. and A. Jensen and Dahl (Christiania) (engines), Actien Gesellschaft für Chromakkumulatoren (Berlin).

Telephone Bills in Parliament.—The National Telephone Company will apply next Session for an Act authorizing them to erect and maintain wires for telephonic communication over streets and other public places, to break up streets, &c., and to erect posts on any street, or other place *within the United Kingdom*. Clauses will be contained in the Bill authorizing the Board of Trade or other public body, in the event of the refusal of the owner or occupier of any land or building to permit a wire or wires to pass over such land or building, to give the required permission; and to make provision "for the full and efficient formation and maintenance of telephonic communication upon such terms, and subject to such conditions, restrictions, and regulations, as may from time to time be prescribed by the Board of Trade or other public body, or local authority, or otherwise, as shall be provided by the intended Act." The New Telephone Company will apply to Parliament for a Bill conferring on them and any County Council

Digitized by Google

or other local authority, powers to make agreements with respect to placing and maintaining posts, &c., in or over any public streets, and the opening up of streets, &c.

Coast Communication.—The following circular, sent us by Mr. J. Lawrence-Hamilton, M.R.C.S., late Honorary President Fishermen's Federation, may prove of interest :—

Including 58 signal stations, the United Kingdom has 680 coastguard stations and detachments (which, in case of war, will be increased by 78 extra stations) within a mile of a telegraph office. At present these 680 coastal stations are locally "near" to telegraph stations, open only from 8 a.m. to 8 p.m., and generally closed all Sunday. It appears that no information has hitherto been collected or published as to the distance of these coastal stations from local telegraph offices, open all day and all night, including Sundays. For defensive purposes during war, and to save life and property at sea, including stranded vessels, both during peace and war, each of these coastal stations should have its coastguards, now numbering 4,200 meu, taught and trained to work telegraph instruments, kept at each coastal station, open day and night without any intermission. These coastal stations should form a complete continuous telegraphic circuit round our coasts and islands, also communicating with lifeboat stations, and with inland telegraph stations, so as to keep the authorities and Lloyd's informed. For 1891-92 the surplus postal profits have been estimated at £3,371,000, part of which should supply the present deficient telegraphic British coastal communication. Even if such charges for a coastal service cost £100,000 or more yearly, the country must have it. However, probably a scheme could be arranged to make such necessary national improvements soon financially self-supporting. The following table shows that these 680 coastal stations are at varying distances, some upwards of 35 miles from the "nearest" local telegraph office, which offices are mostly open only from 8 a.m. to 8 p.m., and closed usually all Sunday.

Under	½	mile,	228	coastal	stations.	Under	15	miles,	29 coastal stations.

Science and Conjecture.—The following extracts from a very apposite article in the *Spectator* of Saturday last will be read with interest in view of recent *ex cathedrâ* deliverances :—"The scientific authorities of to-day have fallen into a rather provoking and tantalising habit of taking the public into their confidence, making known to it discoveries that are as yet only half known to themselves, and building upon the basis of those discoveries a bewildering fabric of conjectural possibilities as to the extraordinary phenomena that may result should the discoveries prove to be true ones. No doubt the really scientific man should have no difficulty in sifting what is actually true from what is only possible; but the unscientific host, to which we confess that we belong, is apt to get rather bewildered by such revelations, and, confusing science with pure conjecture, to believe in all manner of impossibilities and absurdities. For in these days the range of science is so enormously advanced and extended that one must either know a great deal or nothing at all. As it is the work of a lifetime to know a great deal, most people are fain to know nothing at all, and to put a blind trust in those who have the reputation of knowing more than they do. It is natural that the public should swing between too much credulity and too much unbelief. Part of the fault is, as we have said, owing to science itself, which is nowadays a great deal too prone to submit to us discoveries which are but half tested and proved, and to confuse our ignorant minds with wild conjectures. We are ignorant, it is true; but that is not altogether our fault, and we are really anxious to learn. It is annoying, when we are in so humble and expectant a state of mind, that science should dangle before our eyes the most dazzling theories, only to snatch them away again. These are the very 'fairy tales of science.' Let us be prudent; we will neither believe nor will we disbelieve; we will merely wait and see."

The Microphone "Interference" Case.—In a supplement to the *Electrical Engineer* of New York, of November 17th, it is stated that the Edison-Berliner Microphone "Interference" case to which we alluded last week, terminated that day in favour of Emile Berliner. The patent is entitled "Combined Telegraph and Telephone," and is numbered 463,569, and dated November 17, 1891. Berliner's application was filed June 4, 1877, and Edison's, July 20, 1877. In regard to these extraordinary "interference" cases, the *Electrical World* reports that at the next Session of Congress a Bill will be passed to expedite the decision of interference cases occurring in the Patent Office. "It has been obvious for some time," says our contemporary, "that some such step should be taken, for the reason that the procedure of the Patent Office has given great opportunity for abuses, a chance which has been taken advantage of in a large number of cases. The remedy proposed is a somewhat singular one, being nothing less than turning over the interferences to the Circuit Court within 60 days after they are formally declared. An appeal, of course, can be taken to the Circuit Court of Appeals. Under such an arrangement the responsibility would be shifted from the Patent Office to the Circuit Court, and the final decision would be subject only to such delays as generally pertain to cases before that tribunal. The proposition is a specious one, but we very much fear that the result will not be altogether satisfactory. The suggested arrangement will relieve the Patent Office of interferences, but whether it will be able to go further and relieve the public from the improper delaying of patents is quite another matter. In the hands of attorneys anxious for delay, as they would be when delay was to be the purpose of both sides, a case can be made to drag its slow length along for a very considerable period even now, and when the Circuit Court docket becomes crowded with interference cases facilities for killing time will multiply. It is a very difficult matter to hasten the settlement of such questions with entire justice to both parties; we incline to the belief that the proper way of securing this much-to-be-desired end is by changes in the Patent Office practice, rather than by referring the whole matter to the Courts."

Brighton.—As reported in our last issue, the Town Council refused to purchase the goodwill of the Brighton Company's undertaking for £7,000. On the Lighting Committee's report being read, Alderman Sendall asked the Council to adjourn in order that they might discuss the question of the proposed purchase in committee. This motion was put and carried by 17 to 11 votes. The Council adjourned for about two hours, and on the readmission of the Press the Town Clerk said the following resolutions had been passed during the adjournment :—(1.) That the committee report to the Council recommending them not to agree to the purchase of the goodwill and undertaking of the Brighton and Hove Electric Light Company, upon the terms and conditions set out in the report of the Lighting Committee. (2.) That the committee recommend the Council to direct that application be made to the Local Government Board for sanction to borrow a sum of £8,500 for a period of 30 years for purposes of the electric lighting undertaking. These resolutions were carried. —In a letter to the *Sussex Daily News* of Saturday Mr. R. Ballard states that the reasons which led the Council to this decision were :—(1.) That the Council does not approve of paying any money, large or small, to the Company for goodwill or any other purpose. (2.) The Lighting Committee is turning away customers in the streets in the authorised area, but for which they have no funds to supply with cables. In this state of affairs it is not advisable to take over an additional business. (3.) That to take over the Company's business, especially in the outlying districts, would involve an immense capital on the low-pressure system, to which the committee appears up to the present to be wedded. Mr. Ballard urges that an amicable arrangement (not a pecuniary one) should be come to, allowing the Company some degree of permanence in the outlying districts, and some concessions in the authorised area. There would then be two *fairly* competing systems; the price of supply might be agreed on, and the merits of high and low pressure would be tested side by side.—"On grounds of expediency, as well as those of common justice," says the *Sussex Daily News*, "the decision of the Brighton Town Council, on Thursday, with regard to the proposal for purchase of the goodwill of the Brighton and Hove Electric Lighting Company's business is regrettable. . . It is sought to induce the Company to go on doing the unprofitable business, so that directly any portion of it becomes profitable the Corporation may step in and assume it. We have no hesitation in saying that this is neither just nor honourable."

DETECTION OF ELECTRO-MAGNETIC DISTURBANCE AT GREAT DISTANCES.

BY G. M. MINCHIN.

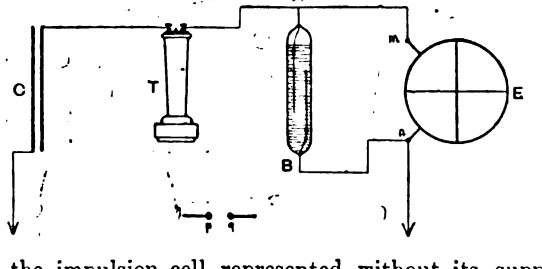
In the *Philosophical Magazine* for last March* I published a Paper giving an account of my work in Photoelectricity; and in this Paper is a description of certain photoelectric cells, which I have called *impulsion cells*. These are small cells, in which the plate which generates the E.M.F. when exposed to light is a piece of tinfoil whose surface must be prepared in a special manner; the liquid in the cell is methyl alcohol.

The most minute mechanical disturbance given to the base or support of the cell will make it insensitive to light if it was previously sensitive, or sensitive if it was insensitive. The cell is connected with a quadrant electrometer, whose indications show whether the cell is sensitive to light or insensitive, without our being obliged to expose the cell actually to light.

In the Paper above mentioned I have stated that when such a cell is in the insensitive condition it can be rendered sensitive by the inductive action of the sparks of a Voss machine or of an induction coil (the cell being shut up in a dark box), and that the induction coil was found to be effective in altering the cell when the distance between them was as much as 81ft. Last September I made a further series of experiments of this nature, and I found that if the coil was removed to a distance of 130ft. from the cell, the sparks were sufficient to make the cell sensitive to light if it had been previously made insensitive by any means. The coil was worked by a few Grove cells, and there was a clear space of 130ft. between it and the cell, no wires intervening. When the distance was increased to 150ft. it could be seen that the sparks held the cell in check, when the latter was started on its insensitive march, but at this distance the inductive effect was not quite sufficient to make the cell actually sensitive.

The cell which I used is one which is rendered insensitive by very minute disturbances. If a puff of air is sent from the lips to the base of the cell, or if the letter *p* is pronounced near it, the cell becomes insensitive. If we repeat to the cell the words "the King of Moab, then, was Balak, the son of Zippor," no effect is produced on the cell until the syllable *por* is pronounced, and then the cell becomes insensitive to light. Indeed, the word *Balak*, if the *B* is pronounced somewhat forcibly, will often make the cell insensitive.

About a month ago I made an experiment which enables us not only to *see* but to *hear* the effect produced on this cell by the electro-magnetic action of the induction coil. It is this experiment which I now desire to make known. The following figure represents the essential features of the arrangement.



I is the impulsion cell, represented without its support (a wooden clamp), its poles, A B, being connected with the poles, *m n*, of a Clifton-Thomson electrometer, E. The pole A is also connected with one pole of a telephone, T, whose second pole is connected with one pole of a condenser, C, the second pole of the condenser being to earth. The pole *n* of the electrometer is also to earth. Finally, *p q* represent the knobs of a distant induction coil.

Now if, either by talking to the cell or by touching its support with a feather, we make it insensitive to light, and then allow it to charge the condenser for a few seconds, on putting the telephone to the ear, and causing the spark to pass between *p* and *q*, we hear a sharp click in the telephone at the instant at which the state of the cell is altered by the electro-magnetic induction.

* See also *The Electrician*, Vol. XXVI., January 23, p. 361.

In the room in which I am working the distance between the cell I and the knobs *p q* is about 14ft., and the click produced by the sudden change in the cell is heard a small fraction of a second before the external sound of the spark travels to the ear.

I have observed these effects even when the distance between the knobs *p q* is less than one-thousandth of a millimetre.

Of course, it is clear that in many respects the part played in these experiments by the impulsion cell is the same as that played by the *spark micrometer* in the experiments of Hertz. (*See* Dr. Fleming's work, "The Alternate-Current Transformer.") But the distances at which the impulsion cell is sensitive to the sparks of the coil are many times greater than those at which the spark micrometer is affected.

As regards the capacity of the condenser, C, which will enable us to hear the click in the telephone, I have found that a condenser of very small capacity will not do—*e.g.*, one formed by two sheets of tinfoil on opposite sides of a plate of glass; but there is not much difference in the sounds produced by a condenser of capacity ·05 and one of capacity 1 microfarad. Also, with some impulsion cells, although the electrometer enables us to *see* that they have been changed by the sparks, the sounds are so feeble that they can scarcely be recognised in the telephone—showing probably that the alteration of their molecular state is comparatively slow. With other cells the clicks are loud enough.

It may also be mentioned that the small sparks obtained from an ordinary electrical gas-lighter, although they are almost surrounded by metal, have been found capable of changing the state of an impulsion cell at a distance of nearly 20ft.

Within the last few days I have made the following most important observation with an impulsion cell. If a Leyden jar of large capacity, or a battery of jars, is connected with the poles *p q* of the induction coil while the cell is in the insensitive state, and if now the spark of the coil is made to pass between *p* and *q*, *no effect is produced on the cell*; but if the Leyden jars are removed, the cell is instantly made sensitive by the spark. This experiment shows that the quickness of the electro-magnetic oscillations is involved in the phenomenon; and to this point I am now devoting attention.

EXPERIMENTAL DETERMINATION OF THE RATE OF PROPAGATION OF ELECTRO-MAGNETIC WAVES.*

BY R. BLONDLOT.

The attempts made to experimentally determine the rate of propagation of electro-magnetic waves have not, we know, attained much success up to the present. I have succeeded in effecting this determination by means of a new method, of which the following is the principle.

Since, as shown by MM. Sarrasin and de la Rive†, it is the resonator which determines the wave length observed, the equation $\lambda = V T$ should be satisfied if we substitute in it for λ and T the values of the wave length and period of vibration peculiar to the *resonator* employed, and for V the rate of propagation of the waves. The determination of this velocity resolves itself, therefore, into a determination of the period of the resonator and the wave length which it picks out. I gave the resonator a particular form in order to determine with certainty the exact period of its oscillations. I will describe one employed by me.

A condenser is constructed out of two circular plates, A′ A″ B′ B″ (Fig. 1), of 6cm. radius, and placed a fraction of a millimetre apart. These two plates are connected by the rectangular circuit A C D E F B, consisting of a copper wire ·184cm. in diameter. The side D E is 10·2cms. long, and the side C D is 6·3cms. long. The total length of the circuit, 32cms, is very small compared with the wave length. It follows that the oscillatory current has sensibly the same value in all parts of the circuit, and consequently we can here apply the formula given by Sir W. Thomson for the discharge of a condenser. More than this, since the current varies extremely rapidly we can, according to a note of M. Lippmann, neglect the resistance

* *Comptes Rendus*, Vol. CXIII., No. 19.
† *The Electrician*, Vol. XXIV., p. 316.

Digitized by Google

and write $T = 2\pi\sqrt{CL}$; where C denotes the capacity of the condenser and L denotes the co efficient of self-induction of the circuit.

I measure C in electro-magnetic units by the classic method of Maxwell, and I determine L as follows:—The current may be considered as closed by the dielectric displacement across the air space separating the two plates of the condenser. This current may be split up into juxtaposed linear currents. Let ds be the length of an element, and i the strength of one of these currents; let ds' and i' be the length and strength of another element, r the distance of these two elements, and ϵ their angle. The potential of the total current is

$$\iint \frac{i\, i'\, ds\, ds'\, \cos\epsilon}{r},$$

this sum, including all the linear elements, constituting the total current. Hertz has, moreover, experimentally shown that the current is entirely localised on the surface of the conductors. The above sum is easily calculated by means of a formula given by M. H. Poincaré.* Having C and L, I deduce the period T.

It only remains to measure λ. As MM. Sarrasin and de la Rive† have shown that λ has the same value in air as in metallic wires, it was permissible to employ this last mode of propagation. By means of my resonator, which is for this purpose provided with a spark micrometer, consisting of a ball soldered to one plate and of a point fixed to the other, and regulated by a screw, I sought the position of the nodes and ventral segments along two wires, M N M′ N′ (Fig. 2), run parallel to each other, as in the experiments of MM. Sarrasin and de la Rive. The resonator shown at P Q is placed so that the long sides of the rectangular circuit are in

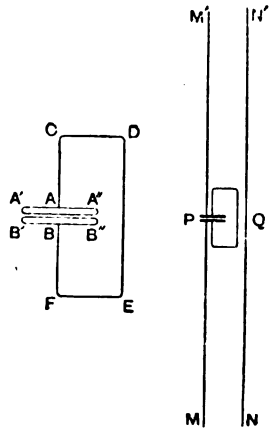


Fig. 1.

Fig. 2.

the same plane as the wires M N, M′ N′, between them, and parallel to them; each side is about ·5cm. distant from its respective wire. The distance between two consecutive nodes gives $\lambda/2$, and more generally the distance between two nodes which comprise n other nodes give $(n+1)\,\lambda/2$.

The following table gives the results of thirteen experiments:

Wave length in metres.	Velocity in kilometres per second.
8·94	299,300
10·90	300,500
11·04	304,100
11·58	301,400
11·60	302,000
14·32	300,800
16·20	298,700
18·30	300,700
18·32	293,400
22·68	288,300
25·72	295,800
27·28	292,700
35·36	291,400
	Mean...297,620

* *Electricité et Optique*, Vol. II., p. 156.
† *The Electrician*, Vol. XXVI., p. 701.

It can be seen that the values of the velocity are concordant although the wave length was varied fourfold. The concordance is as great as the precision of determination of the nodes allows. The experiments were made with resonators in which the dimensions of the rectangular circuit varied from 6·3 × 10·2cms. to 10 × 40cms., and the diameter of the wire from ·184cm. to ·3cm. These quantities have, therefore, no influence on the velocity, although the self-induction which depends on them varied in value from 246·66 to 973·2. We may conclude from the preceding that: *Electric undulations have only one rate of propagation independent of the wave length, and approximately 279,600 kilometres per second.*

The number determined is within the limits of experimental error equal to the ratio of the electro-magnetic and electrostatic electrical units, as is indicated by Maxwell's theory, and also to the velocity of light. It would be rash to conclude from this equality that electro-magnetic vibrations are of the same nature; nevertheless, we cannot ignore the fact that the result obtained is favourable to this hypothesis.

THE SIEMENS CABLE TRANSFORMER.

On the occasion of the reading of Dr. Fleming's Paper, "On some Effects of Alternating Current Flow in Circuits having Capacity and Self-Induction" before the Institution of Electrical Engineers in May last, allusion was made to some very instructive experiments which had taken place in April of the previous year at Messrs. Siemens Bros.' Works. A Siemens W

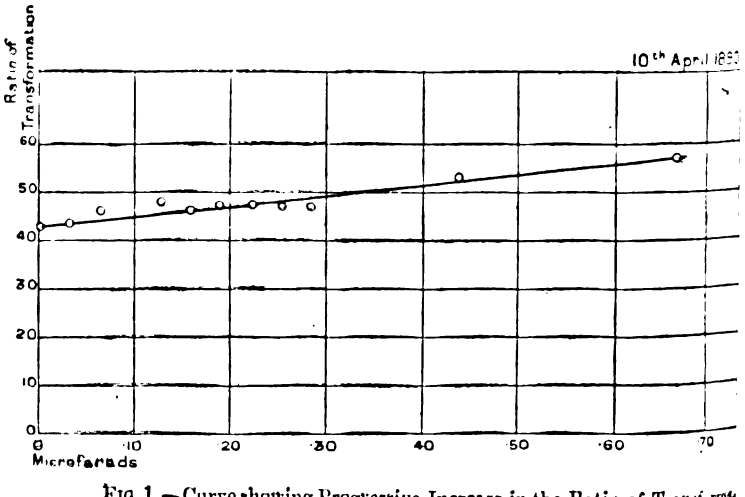

Fig. 1.—Curve showing Progressive Increase in the Ratio of Transformation of a No. 2 Siemens Closed-Circuit Transformer as the Capacity of the Secondary was increased.

alternator was run at constant speed and constant excitation, and connected to the thick-wire circuit of a No. 2 Siemens transformer, the fine-wire circuit of which was connected to a gutta-percha insulated single-conductor cable, the far end of which was free, placed in a tank of water. The length of cable in circuit was varied, and the resulting variations in the primary and secondary volts observed; and it was found that not only were the secondary volts three and a half times their normal value when a certain critical value was given to the capacity, but that the ratio of transformation *increased progressively* from 1:45 to 1:57 as the capacity was increased from zero to ·65 microfarad (see Fig. 1, reproduced from *The Electrician* of May 8, 1891). In the course of the discussion it was stated by Mr. Alexander Siemens that the particular alteration of the ratio of transformation referred to only applied to that particular type of transformer; and that his firm had found that if the form of transformer was altered the ratio of transformation remained absolutely the same, while the capacity of the secondary circuit was varied over a wide range. The transformer mentioned by Dr. Fleming was of the closed magnetic circuit type, and Mr. Alexander Siemens showed the curve (Fig. 2) deduced from experiments with an open-circuit "cable" transformer, from which it can be seen that the ratio of transformation remained constant at 23·5 throughout. It must, however, be remem

Digitized by Google

bered that the volts do not fail to vary, although their ratio may remain constant. In the curves of the primary and secondary pressures shown at the same time it could be seen that there were huge variations in each circuit as the electrostatic capacity was altered.

The Siemens "cable" transformer consists of a long core of wire rope, composed of soft iron wires, covered with a layer of specially-prepared insulating material, around which are wound two insulated conductors, forming one the primary and the other the secondary circuit of the transformer.

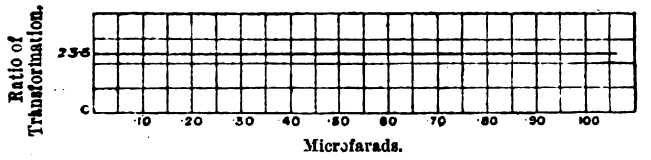

FIG. 2.—Siemens Open-Circuit "Cable" Transformer. Curve of Transformation Ratio when Capacity of Secondary is increased.

The illustrations (Figs. 3 and 4) show, in plan and elevation, a transformer of this construction coiled and fixed for use in a skeleton stand, with the terminals of the primary and secondary circuits arranged on the top. For various purposes,

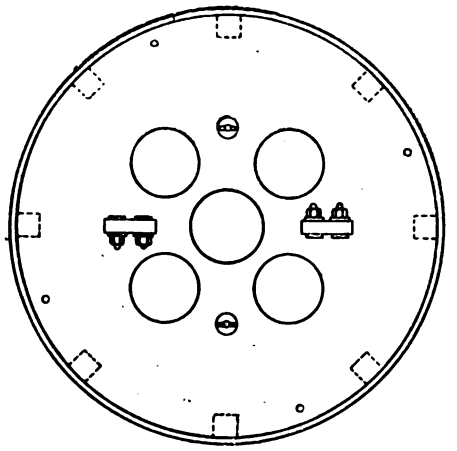

FIG. 3.—Siemens "Cable" Transformer. Plan.

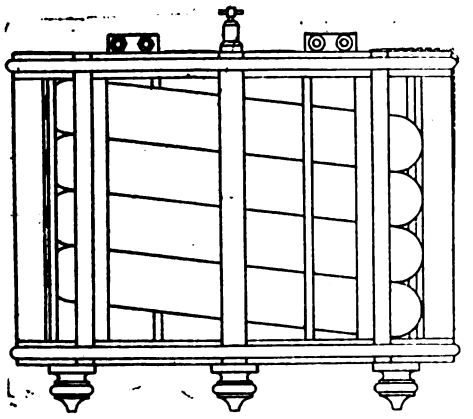

FIG. 4.—Siemens "Cable" Transformer. Elevation.

especially for central or sub-station work, it would probably be more convenient not to coil the transformers, but to lay them out straight or suspend them in a more or less horizontal or vertical position; but bending does not in any way affect their magnetic qualities. The dimensions of the iron core and conductors, and the quality of the iron, are so chosen that while the cooling surface of the transformer is much larger than in transformers of the ordinary type, there is very little heat generated by hysteresis, by eddy currents, or copper resistance. They, therefore, keep very cool, even when working at full load. They vary somewhat in efficiency, according to their size. They are, however, designed to work with a high efficiency at light loads, so that when they are used in central or sub-stations, or elsewhere, where the load is subject to great variations during the day, their average, or all-day, efficiency shall be as high as possible. For example, the 150 H.P. transformer would have 94 per cent. efficiency at full load, between 93 and 94 per cent. at half load, and 90 per cent. at a quarter load. Moreover, they are self-regulating, as regards their terminal pressure, within 3 or 4 per cent. of the normal pressure. The transformers are designed to transform from 2,500 to 100 volts, or *vice versâ*, and for a frequency of 100 ∿ per second.

ELECTRIC LIGHT AND EYESIGHT.

A short discussion has recently appeared in the columns of the *Morning Post* on the effect of electric light on the eyes. The first letter (on the 17th inst.) commenced with the very reasonable and proper statement that "the electric light is an admirable invention, but like many new inventions but very imperfectly understood." The correspondent continues to say that "unless electric light be softened by shades it is most injurious, and in cases of weak sight absolutely pernicious." Even this assertion is not too strong if it is taken as relating to the senseless way in which electric lights are too often placed. More than one case of this nature is described in vigorous language by Mrs. GORDON in her "Decorative Electricity," and some of her remarks were quoted in our review of that work (*The Electrician*, Vol. XXVI., p. 670). But the correspondent to the *Morning Post* should remember the advice given by a well-known judge to a junior: "Give your opinion, it will probably be right; reserve your reasons, they are sure to be wrong." He goes on to say that "if electric light be placed high, as it is in most houses and theatres, it should never be used at full power unless completely softened by shades of yellow, green, or blue." This suggests that there is something injurious in the nature or quality of the light, and that tinted shades will cure this evil. Red or pink shades are apparently excluded, and we have therefore no hesitation in putting down this correspondent as a member of the unfair sex. Rosy shades may sometimes be tawdry or even meretricious; but, when they allow enough light to pass they produce no disagreeable result, and they offer certain advantages on which it is unnecessary to dwell. But it is just in those cases in which the lamps are high, that the use of shades is less valuable. With the exception of an arc or a lime-light, no lamp has so great an "intrinsic brightness" as a glow-lamp giving its full candle-power. This simply means that the light-giving surface is very small. If lamps are arranged so that the filaments are visible, dazzling and dis-

Digitized by Google

comfort will naturally ensue. One way out of the difficulty is to place them so high that the eye need rarely rest on them. The alternative is to screen them in those directions in which they may be seen. The word "shade" is used in a loose way, sometimes signifying such reflectors as are used over billiard tables, where the lamp is completely hidden; and sometimes, a translucent medium of glass or silk which is interposed to soften the light. If glow-lamps are placed high enough no softening is necessary, especially if light-coloured or white reflectors are used. If they must be placed low, the direct light must either be softened or completely screened. For reading, with a light set low, an opaque reflector or screen is essential, and yet how often is this common-sense precaution neglected! Any person of the most ordinary intelligence must see the folly of trying to read by a bright light close to the book, and without any shade, if they give the matter a moment's consideration. But no; they allow themselves to be half blinded, and then write to the papers. The arrangement of the lights in the Law Courts was criticized by another correspondent, who remarked that they are "hung so low and in such a manner that from the body of the Courts it is impossible to look at either the Bench, the jury, or the witness box, without having groups of lights shining full on the eyes." The lighting of the Law Courts was one of the earliest examples of illumination by glow-lamps, and there was little previous experience to go upon. The fittings are neat and in keeping with their surroundings, which is more than can be said for most of the "art" fittings of the present day. If the authorities will sanction a little re-wiring the arrangement might be considerably improved. The present defects are simply the fault of the man who, with pardonable inexperience, settled the positions of the lamps.

The correspondence to which we have alluded suggests that there is something aggressively pernicious in the nature and quality of electric light, and a most alarming and extravagant description was given of the well-known effects of arc lamps at close quarters on the eyesight of those who have to deal with them; and this was coolly put forward as "a statement which shows how great an abuse the electric light may become." Hundreds of our readers have, during their training, rashly exposed themselves to the light of arc lamps while engaged in testing or adjusting them; and though provided with dark glasses for actually inspecting the arc, have incautiously omitted to protect their eyes during their general work. Not much discomfort is felt at the time, but the sufferer generally begins to be aware of the mischief on going to bed; he has the sensation of sand under the eyelids. The pain is sometimes very severe, and sleep is often out of the question; but generally the irritation has passed off by breakfast time next morning, and the doctor is rarely consulted. But to bring forward this as a general argument against the use of electric light is arrant nonsense; and the exaggeration of the description given may be judged from the opening statement, "At certain works in France an electric arc is used which is more than equal to 100,000 candles." There is probably no arc lamp in existence giving more than 25,000 candles.

As far as the colour of electric light is concerned there is no quality or character that can possibly elude the analysis of the spectroscope. It would be possible to produce an apparently pure white light by mixing green and red or blue and yellow rays; and though apparently perfectly white, this light might tire the eyes by stimulating only a portion of the nerves. But the glow-lamp gives a light of precisely the same quality as a good lamp or gas flame, and the arc gives a more perfect, that is to say, a more nearly white light, but (*pace* the lamp makers) is not always perfectly steady. This brings us to a real defect which may occasionally exist, and one which has not, as far as we are aware, received careful attention. The light of lamps driven direct from small gas engines, without accumulators, is rarely steady. The irregularity has never, to our knowledge, been estimated except by the eye. A very slight variation, almost, or perhaps quite, imperceptible when looked for, may prove very tiring after an hour or two. It is highly improbable that there is any variation in the light of a glow-lamp corresponding to the frequency of an alternating current. There is certainly none that can be seen by mere inspection. A revolving mirror or a very delicate selenium photometer might settle the question by a physical measurement. A far more likely variation is that due to the beat of the engines.

Some physical measurements should be made in order to discover whether the light supplied by the leading companies is steady or not. The voltmeters give a satisfactory proof that there is nothing serious amiss; but the light of a glow-lamp varies one per cent. for a variation of one-fifth per cent. of the volts. If such a variation occurs at every stroke of the engine it would be practically imperceptible to the eye; and though not invisible on a good voltmeter, it could only be measured by special apparatus. The grumblers are in a very small minority, and it may be questioned whether it is worth while to make the investigation. The blinking which takes place on supply systems where alternators are not or cannot be run in parallel only takes place when it is necessary to change a main over from one machine to another. This is done so seldom in a well-regulated station that it need not be considered. We have never heard that the beats of the engines are visible on the glow-lamps; but it is quite possible that a variation may occur which is not directly visible, but produces some physiological effect which when prolonged may give rise to discomfort. This conjecture is thrown out in the endeavour to find some reason for these complaints. It is all very well for ignorant fault-finders, with their superficial chatter, to make irresponsible criticisms; but electrical engineers are even more ready to remove any defects than these prattlers are to sit in judgment.

REVIEWS.

A First Book in Electricity and Magnetism. By W. Perren Maycock. (London: Whittaker and Co. 1891.)

Were it not for the lists of questions following each chapter this would be an excellent elementary handbook for the general reader. As it stands, it must be considered as a text-book. We notice a rather neat analogy between electrical potential and wealth:—

"Let us consider a number of men. So long as every man had the same amount of money there would be no rich or poor amongst them. But directly one man got more money than any of the others, he would become rich as compared with them. On the other hand, if one of them parted with some of his share, he would become poor as compared with the rest. While every man has an equal amount of money, the idea of riches or poverty does not exist. When every body has its proper share of electricity, electricity is not apparent. When a man gets more than the average share of money, he becomes rich—his value is increased. When a body has a surplus of electricity, its potential is raised above the average, *i.e.*, above the potential of the earth. When a man parts with some of his money, he becomes poor—his value is decreased. When a body has less than its proper share of electricity its potential is lowered beneath that of the earth."

Few analogies will bear much pressing, but some of our readers may find amusement in considering the idea of argento-motive force, and in discovering financial analogues for self-induction and polarization.

A Guide to the Unprotected in Every-day Matters relating to Property and Income. By a Banker's Daughter. Sixth edition, revised. (London: Macmillan and Co. 1891.)

It is not often that we have to notice a book written by a lady, and still more rarely one that is addressed to widows and single ladies. Neither technical education (of the scientific character to which we are accustomed) nor the experience of a pupil in engineering works teaches him how to draw a cheque, or what to do with a crossed one; and he will, as a rule, have much clearer ideas about slide valves than preference shares, knows more about commutators than mortgages, and would be much better able to execute a working drawing than a will. If he has no opportunity of picking up casual information he sometimes does not like to ask about "every-day matters," and even if he gets verbal assistance he cannot expect to get what this little book will give him, viz., between 50 and 60 specimen business letters. We have often consulted a previous edition of this book, and have found it to be of much more extended use than the very modest preface suggests. One excellent feature is that it begins at the very beginning, and no detail is considered by the authoress as unworthy of attention. The matters with which this little work deals come so naturally to commercial men that they generally have but little idea of the difficulty with which beginners learn them. The present edition is revised up to date; but we think that the scope is too modest, and that additional chapters should be given with extended information about promissory notes, and on the whole duty of an executor.

Pioneers of Electricity. By J. Munro. (London: The Religious Tract Society. 1890.)

The pioneers selected by the author are Thales, Gilbert, Franklin, Coulomb, Volta, Davy, Oersted, Ampere, Ohm, Faraday, and Maxwell. Brief biographical sketches, accompanied in most cases by portraits, describe in plain language the leading discoveries of these men, and some interesting incidents and anecdotes are given. It is pointed out in the preface "that seven of these investigators—that is, the majority—were disposed to cultivate the art of poetry."

Heroes of the Telegraph. By J. Munro. (London: The Religious Tract Society. 1891.)

Forming a sequel to "Pioneers of Electricity" this book contains some account of Wheatstone, Morse, Sir W. Thomson, Sir W. Siemens, Fleeming Jenkin, Reis, Graham Bell, Edison, and Prof. Hughes. In an appendix shorter notices are given of Gauss, Weber, Cooke, Bain, Werner Siemens, Latimer Clark, Du Moncel, and Elisha Gray. The author does not attempt to define a hero; and any heroic acts that may have been achieved by any of these men have not, so far as we know, or can learn from this book, any connection with telegraphy. The author's trouble in collecting these anecdotes and details might much better have been spent in searching for some of the unrecognised work of those who have toiled and received no reward. It is true that his account of Morse gives a fair share of praise to Vail, enough, indeed, to throw Morse to the background to no small extent. Mr. Munro tells us little, if anything, about these pioneers that enhances their already well-earned reputation; and we hope that he will some day give an account of the forgotten or too little appreciated work of men whose names are seldom mentioned; and that he will do for them what others have done for Henry, Sturgeon, and Gilbert.

Leitfaden zur Construction von Dynamomaschinen. By Dr. Max Corsepius. (Berlin: J. Springer. 1891.)

The calculations in this guide for designing dynamos are considerably obscured, firstly by being printed in some parts in two columns in order to save space, and secondly by the allowances for various losses being made simply by alterations in the original figures, no indication whatever being given as to the reason for, or mode of arriving at such alterations. This latter defect is sufficiently serious to make the reasoning perfectly unintelligible to anyone who has not sufficient knowledge of the subject to be able to do without a guide. A wiring table is given at the end of the book, but it presents no new features of any value.

SOME CURVES FROM ALTERNATING-CURRENT MACHINES.*

BY WARREN B. LEWIS.

The unusual number of experiments which have been made within a year or two upon the characteristic curves of currents as obtained from different types of dynamos, led the writer to attempt a few investigations in the same line, upon some alternating machines of special design. Taken in connection with preceding results, which have been published from time to time, they afford a most interesting study of dynamo-electric machines of this class, and give a more or less complete record of the peculiarities which may be obtained by different dispositions of iron and copper.

The applications of alternating currents to methods of heating, smelting, and other processes in which currents of immense volume are employed, has led to a class of apparatus considerably different from that which is so generally known and used for lighting. In the transmission of these currents obstacles have arisen which have been satisfactorily overcome only after considerable experimenting. The adaptability of the transformer to such processes has led to a large number of interesting experiments and developments, and has called for a dynamo to be used in connection with these transformers which possesses peculiarities not found in other types.

A combination of mechanical and electrical requirements has imposed conditions, some of which, if understood at the outset, may lead to a better comprehension of the results which follow.

In the construction of the transformer it has been found preferable, for many reasons, to make the secondary a large copper casting, which generally means a more or less solid mass of metal; but, in transmitting currents of several thousands of amperes, there is made evident the fact that the superficial area is of the greatest importance, and that the interior mass is of little use. This phenomenon being dependent largely upon the rate of alternations, the system could be made more efficient by using a low periodicity. The requisite induction in the armature wires can be obtained by causing a very rapid change in the magnetic circuit at some instant; and in the machines under observation this is so well done that only a remarkably small amount of wire is used. One would naturally expect that with an abnormal rate of change in the magnetic circuit at one point, a slower change would occur at some other place, and that the result would be a curve rather far removed from the typical sine curve. How closely the theory is proved by practice will be seen by reference to the curves.

The periodicity adopted was 50 per second, obtained from four and six pole machines. The two machines which were principally used in the trials are both six-pole, but of different designs as to the angular width of the pole pieces. The armatures of both are solid, with the exception of the ventilating holes, and have pole pieces corresponding to the field poles. The armature wire is wound in rectangular coils and put over the poles so as to surround them.

One machine, which will be designated as a "60," was a 60,000 watt dynamo of the composite type. A certain proportion of the armature current is commutated, and flows through the field wire in series with the current of a small exciter dynamo. The proportion commutated is dependent upon the ratio of the resistance of the exciting circuit to a shunt placed outside of the machine, and connected to a third collector ring.

Another machine was a separately excited dynamo, rated at 40,000 watts, and will be designated as a "40." This machine differs from the preceding in the angular width of the pole pieces and the shape of the grooves in the armature core. The third was a separately excited alternator, the armature having no iron, and will be designated as a "50."

In connection with each set of curves a small diagram is given, showing the relative dimensions of the various parts, and their angular positions. A description of the apparatus used is hardly necessary, as the same arrangements have been described in previous Papers. The galvanometer was a ballistic one, designed and constructed for the occasion, and gave excellent results.

In all the curves the abscissæ are actual degrees about the shaft of the machine, and ordinates the volts and amperes as marked. The position of the field poles with relation to the centre of the armature coil is also shown at the top and bottom of curves 1, 2, 3, 4, 5, 6, and by the dotted ovals in curve 7.

Curves 1, 2, 3 are of the type "60." The angular width of the pole pieces is shown in diagram 1 to be 40 degrees, and the space between them 20 degrees. The direction of rotation of the armature is indicated in each curve by an arrow.

In curve 1, the full line is the potential curve, the dynamo running on no load. The dotted curve is a sine, and is drawn to more forcibly illustrate the approach of the potential curve to a "saw tooth." The features which become noticeable are the regularity of the curve and its maximum E.M.F., which is about 468 volts: the working potential, as read on a Cardew voltmeter, being

* From the *Electrical World* (New York).

Digitized by Google

296 volts, shown by a straight line. The field magnets required 386 watts, which were supplied by the small exciter alone, evidently.

Observe now curve 2. The dynamo is loaded on a water rheostat to a little over 52,000 watts, the field requiring 635 watts, or about

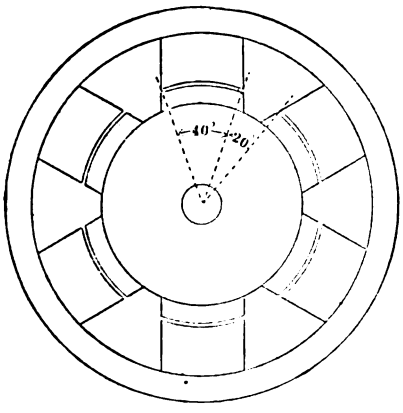

Diagram 1, "Type 60"

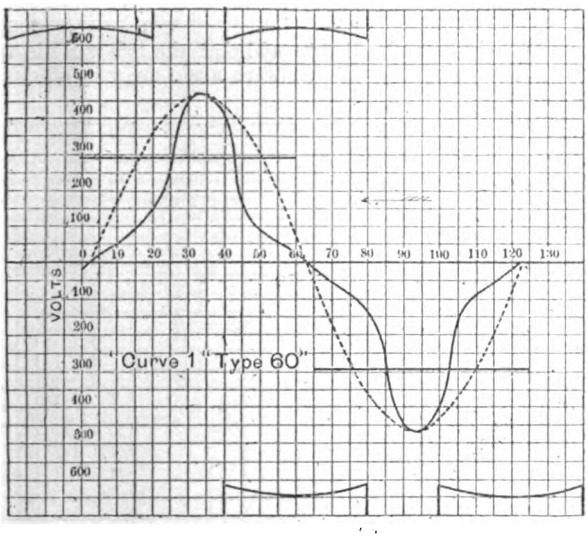
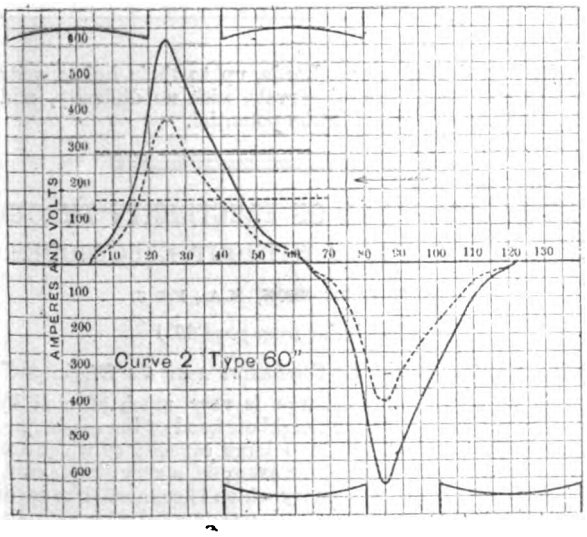
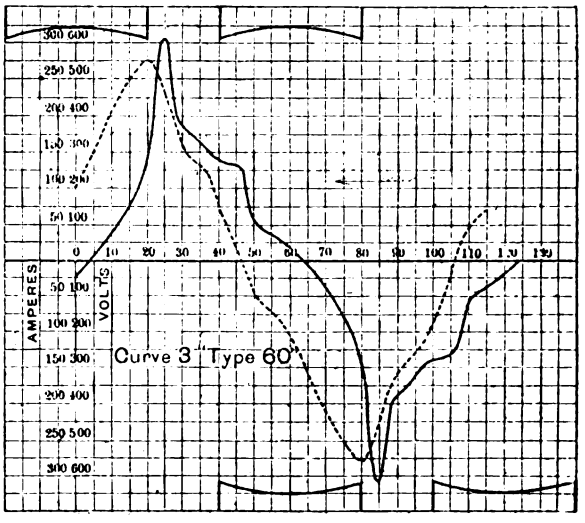
1·2 per cent. The regularity of the curve has been considerably disturbed, and the maximum point has reached 615 volts, while



the working potential has increased but 8 volts to 304. The dotted curve is the current curve, the straight dotted line the current as read on an ammeter, both drawn to the same scale as the potential curve. This makes rather a curious curve when compared with curve 1, but graphically illustrates the change in the magnetic



circuit very clearly—the sudden jumping away from the armature of the magnetic lines from the receding poles, and the leap to the armature of the lines from the approaching poles. But the peculiarity becomes greater when the load is an inductive one. Curve3 is such a load, the actual power being 34,500 watts. The maximum E.M.F. is the same as when a non-inductive load was used, and the side of the curve in the direction of rotation is not greatly changed; but the remaining part of the curve baffles



description. The current curve is quite regular, and approaches a sine curve, which is what an inductive load tends to produce, as is

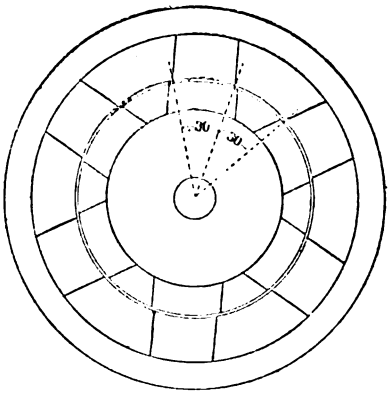


Diagram 2 "Type 40"

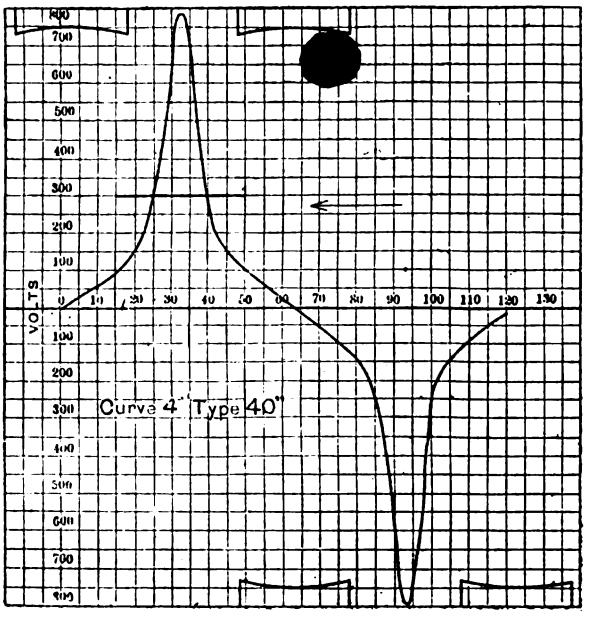
well known. The field magnets use 826 watts, or 2·4 per cent. of the output.

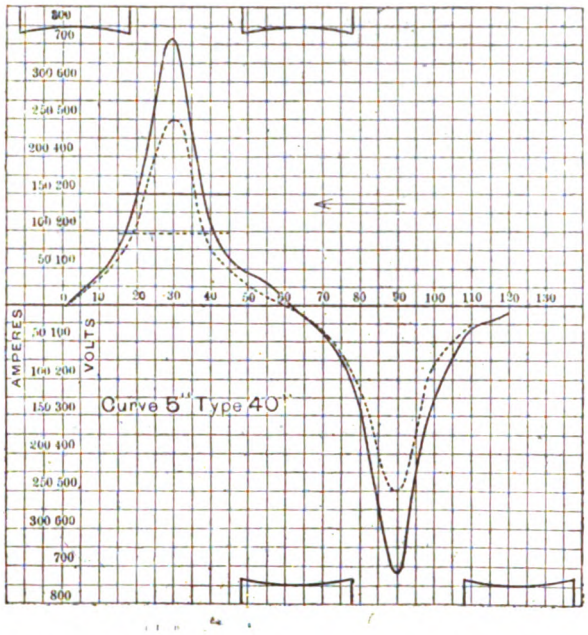


Referring now to curves 4, 5, 6, we see the effect of narrowing the pole pieces. This machine is the type "40," and the pole pieces, as shown in diagram 2, are but 30 degrees in width. The working potential being practically the same as in the case of the

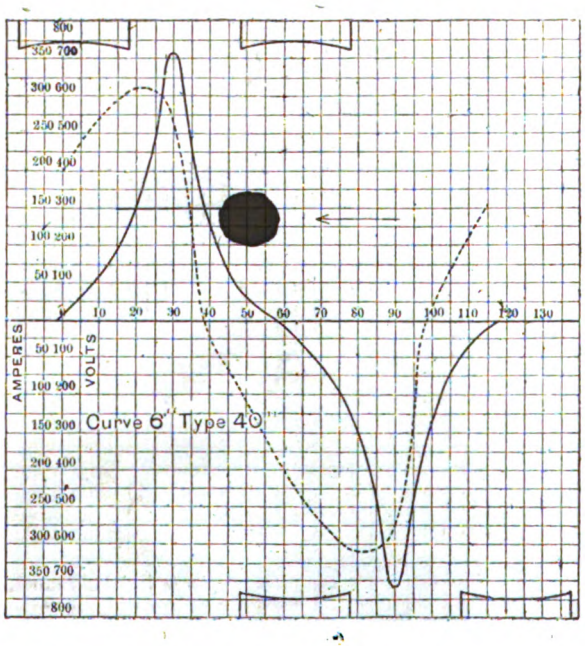
Digitized by Google

"60," namely, 300 volts, the maximum attained is 790 volts, with a position exactly midway between the poles, and very rapidly falling off, about equally on either side. It may be interesting to note the matter of insulation which this curve brings out. Although 300 volts is the working potential, the machine should be insulated for 800. As a fact these dynamos are now insulated to withstand a potential of 1,800 volts.

Curve 5 represents a non-inductive load of 34,000 watts, the fields using 936 watts. The angular position of the maximum point



has advanced, but the regularity is still preserved, with the exception of a few degrees near the zero line on one side. The curve has broadened, too, with a consequent drop in the maximum E.M.F. As would naturally be expected, the current curve follows the potential curve very closely. Curve 6 was taken when the dynamo was loaded with an inductive resistance, the same as in curve 3. The actual power was 37,000 watts, with 1,140 used in the fields. Notice that the current lags somewhat more than in the "60."



Curve 7 was made principally to show how far removed in character two machines of so different design could be. Diagram 3 shows the relation of armature and field, the dotted ovals being the field poles, and the full lines the armature coils. The dotted curve in curve 7 is a sine and serves to show how near the curve of the dynamo in question approaches it. Compare this with curve 4, and a greater difference could hardly be imagined.

Unfortunately, at this point, circumstances prevented the continuation of the experiments, and it is a matter of regret that further curves could not be taken on the last machine. A few rough experiments were made to determine the reaction of an armature pole upon a field pole, when the dynamo was carrying its full load, but the effect was so small that special arrangements would have had to be made, and for lack of opportunity the work was discontinued.

A very interesting study may be made by recalling the curves made by Messrs. Tobey and Walbridge,* on the "Stanley Arc Alternating Current Machine," and comparing them with those given in the preceding.

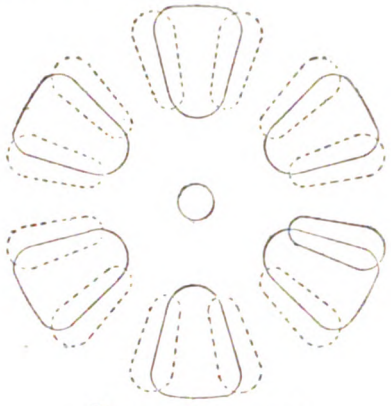


Diagram 3, "Type 50"

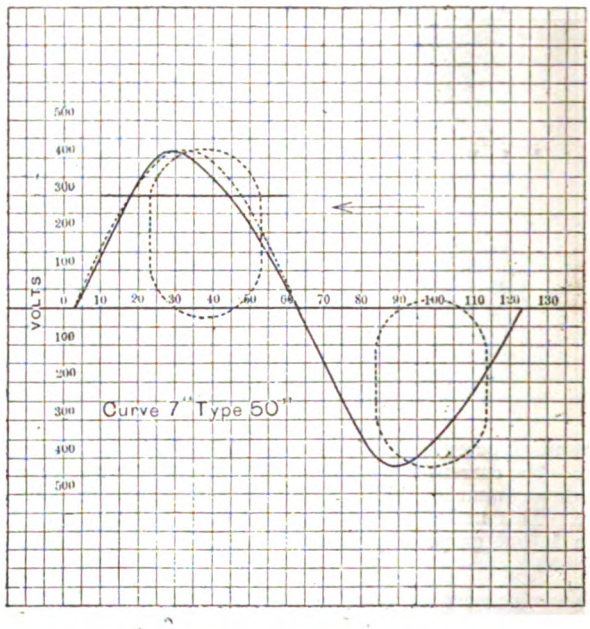
It may not be out of place to add that the two machines upon which the foregoing experiments were made are very efficient and



well suited to the purpose. Loads, up to their full capacity, are thrown on and off at brief intervals, with no difficulty, and with hardly a noticeable change in the potential.

ON THE DISCHARGE OF ELECTRICITY THROUGH EXHAUSTED TUBES WITHOUT ELECTRODES.†

BY J. J. THOMSON, M.A., F.R.S.

(Concluded from page 69.)

On the Effect produced by Conductors near the Discharge-Tube.

The intensity of the discharge is very much affected by the presence of conductors in the neighbourhood of the discharge-tube, especially conductors which have large capacity or which are connected to earth. Let us take, for example, a very simple case, that of a bulb surrounded by a primary which is connected to earth; in this case the approach of the hand, or any conductor connected to earth, will make the discharge brighter and at the same time less well-defined at the edges; touching the tube, though this is already connected to earth, produces a very marked effect in increasing the

† Abstract from the *Phil. Mag.*, October, 1891.

Digitized by Google

facility of the discharge. We can, I think, understand the reason of this if we consider the behaviour of the tubes of electrostatic induction. When the spark passes, these tubes (see *The Electrician*, November 6th, p. 14) rush out from the jars and make for the primary; in their journey to the primary they pass through the bulb and produce the discharge. Let us suppose now that there is a large conductor situated somewhere near the bulb; the tubes, as before, rush from the jar to the primary, but in doing so some of them strike against the conductor; the tubes which do so lose the portion inside the conductor, acquire two ends each on the surface of the conductor. and swing round until they are at right angles to its surface; they remain momentarily anchored, as it were, to the conductor, and if the conductor is in the neighbourhood of the bulb, they will in general help to increase the maximum density of the tubes passing through the bulb. Though these tubes may not approximate to closed curves, and so directly produce a ring discharge, they may readily facilitate this discharge indirectly; for even those tubes which go radially through the bulb may produce a glow-discharge from the glass into the bulb, and may thus furnish a supply of dissociated molecules through which the ordinary ring-discharge can pass with much greater readiness. For nothing is more striking than the enormous difference produced in the electric strength of these rarefied gases by the passage of a spark. It is sometimes difficult to get the discharge to pass at first, but when once a spark has passed through the gas, a spark-length one quarter the length of that necessary to originate the discharge will be found sufficient to maintain it.

It is sometimes convenient, in cases where difficulty is found in starting the discharge, to avail ourselves of this property by connecting the mercury of the pump to which the tube is attached with one terminal of an induction coil, the other terminal of which is put to earth. When the induction coil is in action, a glow-discharge fills the pump and tube, and while this glow exists the

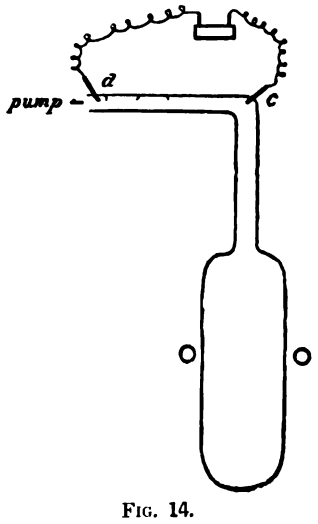

FIG. 14.

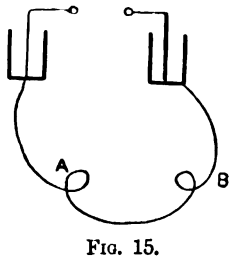

FIG. 15.

electrodeless discharge can easily be started; once having been started, it will continue after the induction coil is stopped. An experiment of this kind, which I had occasion to make, gave very clear evidence of the way in which dissociated molecules are projected in all directions from the negative electrode in an ordinary discharge-tube, but not from the positive. The discharge-tube was fused on to the pump, and at an elbow two terminals, *c* and *d*, Fig. 14, were fused into the glass; these terminals were connected with an induction coil, and the pressure in the tube was such that the electrodeless discharge would not start of itself. When the coil was turned on so that *c* was the negative electrode, the electrodeless discharge in the tube at once took place, but no effect at all was produced when *c* was positive and *d* negative. We may thus regard the effect produced by the presence of a conductor as due to the conductor catching the tubes of electrostatic induction, and concentrating them on the discharge-tubes. These tubes in many cases acting indirectly by producing a glow-discharge through the tube, which, by diminishing the electric strength of the gas, makes discharges of any other kind very much easier. Though the presence of a conductor near the discharge-tube will, in general, concentrate the tubes of electrostatic induction on the discharge-tube more than would otherwise be the case, yet this does not always happen. When in some positions the conductor may hold back for a time from the discharge-tube tubes of electrostatic induction which would otherwise pass through it, and thus diminish the maximum density of the tubes of electrostatic induction in the discharge-tube, and hence tend to stop the discharge. I have frequently met with cases where the presence of a conductor diminishes the intensity of the discharge. One of the most striking of these is when the two jars are insulated, and a square discharge-tube used. The spark was adjusted so that the discharge just, but only just, went round the tube. A sphere connected to earth was then moved round the discharge-tube; in some positions it increased the brilliancy of the discharge, and the tube became quite bright, while in other positions it stopped the discharge altogether.

The observation of the behaviour of the discharges through these tubes is a very convenient method of studying the effect of conductors in deflecting the flow of the tubes of electrostatic induction which fall upon them; for the appearance of the discharge is affected not merely by the average, but also by the maximum value of the electromotive intensity which produces it. Thus a high maximum value, lasting only for a short time, might produce a discharge, while a more equable distribution of electromotive intensity having the same average value might leave the tube quite dark.

I have employed these discharges to study the behaviour of bodies under the action of very rapid electrical oscillations in the following way. In the primary circuit connecting the outside coatings of the jar, two loops A and B (Fig. 15) were made, in one of which, A, an exhausted bulb was placed, the spark-length and the pressure of the gas on it being adjusted until the discharge was sensitive, *i.e.*, until a small alteration in the electromotive intensity acting on the bulb produced a considerable effect upon the appearance presented by the discharge. The substance whose behaviour under rapid electrical vibrations was to be examined was placed in the loop B. The results got at first were very perplexing, and at first sight contradictory, and it was some time before I could see their explanation. The following are some of these results. When a highly exhausted bulb was placed in B a brilliant discharge passed through it, while the discharge in A stopped. A bulb of the same size, filled with a dilute solution of electrolyte, produced no appreciable effect; when filled with a strong solution it dimmed the discharge in A, but not to the same extent as the exhausted bulb. A piece of brass rod or tube increased the brightness of the discharge in A; on the other hand, a similar piece of iron rod or tube stopped the discharge in A at once. The most decided effect, however, was produced by a small crucible made of plumbago and clay; this when put in the loop B stopped the discharge in A completely. I found, however, that by considering the work spent on the substance placed in B, the preceding results could be explained. When a large amount of work is spent in B, the discharge in A will be dimmed, while no appreciable effect will be produced on A when the work spent in B is small. Now let us consider the work done in a secondary circuit whose resistance is R, whose coefficient of self-induction is L, and which has a coefficient of mutual induction M with the primary circuit. If the frequency of the current circulating in the primary is p, we can easily prove that the rate of absorption of work by the secondary is proportional to

$$\frac{R M^2 p^2}{L^2 p^2 + R^2}.$$

Thus the work given to the secondary vanishes when R = 0 and when R = infinity, and has a maximum value when $R = Lp$. Thus the condition that the secondary should absorb a considerable amount of work is that the resistance should not differ much from a value depending on the shape of the circuit and the frequency of the current in the primary. No appreciable amount of work is consumed when the resistance is very much greater or very much less than this value. I tested this result by placing inside B a coil of copper wire. When the ends were free, so that no current could pass through it, it produced no effect upon the bulb in A; when the ends were joined so that there was only a very small resistance in the circuit, the effect was, if anything, to increase the brightness of the discharge in A. When, however, the ends were connected through a carbon resistance which could be adjusted at will, the discharge in A became very distinctly duller when there was a very considerable resistance in the circuit. This experiment confirms the conclusion that to absorb energy the resistance must lie within certain limits, and be neither too large nor too small.

We can now see the cause of the differences observed when the substances mentioned above were put into B. The brass rod and tube did not dim the discharge in A, because their resistance was too low; the weak solution of electrolyte, because the resistance was too great; while the resistances of the crucible and the strong solution of electrolyte which obliterated the discharge from A were near the value for which the absorption of energy by the system was a maximum.

The case of iron is very interesting because it shows that even under these very rapidly alternating forces, iron still retains its magnetic properties. A striking illustration of the difference between iron and other metals is shown when we take an iron rod and place it in B, the discharge in A immediately stops; if we now slip a brass tube over the iron rod the discharge in A is at once restored. If, on the other hand, we use a brass rod and an iron tube, when the rod is put in B without the tube the discharge in A is bright; if we slip the iron tube over the rod, the discharge stops.

Digitized by Google

To compare the amount of heat produced in the brass and iron secondaries, Prof. Thomson considers mathematically the case of an infinite cylinder exposed to an external magnetic force; and he arrives at the conclusion that for iron and copper cylinders of the same dimensions the waste in heat is about 70 times as much in iron as in copper, assuming that the iron retains its magnetic properties under these very rapidly alternating forces. The result explains the effect of the iron in stopping the discharge. As I am not aware that any magnetic properties of iron under such rapidly alternating forces have been observed, I was anxious to make quite sure that the difference between iron and brass was not due solely to the differences between their specific resistances. The first experiment I tried with this object was to cover the iron rod with thin sheet platinum, such as is used for Grove cells. As the resistance of platinum is not very different from that of iron, if the effect depended merely upon the resistance, slipping a thin tube of platinum over the iron ought to make very little difference. I found, however, that when the platinum was placed over the iron, all the peculiar effects produced by the latter were absent, thus showing that the effect is not due to the resistance of the iron. It then occurred to me that I might test the same thing in another way by magnetising the iron to saturation, for in this state μ is nearly unity; thus if the result depended mainly on the magnetic properties of the iron it ought to diminish when the latter is strongly magnetised. I accordingly tried an experiment in which the iron in the coil B was placed between the poles of a powerful electromagnet. When the magnet was "off" the iron almost stopped the discharge in A; when it was "on" the discharge became brighter, not indeed so bright as if the iron were away altogether, but still unmistakably brighter than when it was unmagnetised. This experiment, I think, proves that iron retains its magnetic properties when exposed to these rapidly alternating forces.

Another result worthy of remark is that though a brass rod or tube inserted in B does not stop the discharge in A, yet if a piece of glass tubing of the same dimensions is coated with Dutch metal, or if it has a thin film of silver deposited upon it, it will stop the discharge very decidedly. We are thus led to the somewhat unexpected result that a thin layer of metal when exposed to these very rapid electrical vibrations may absorb more heat than a thick one. I find, on calculating the heating effect in slabs of various thicknesses, that there is a thickness for which the heat absorbed is a maximum.

The slight increase in the brightness of the discharge in A when a brass rod is placed in B is due, I think, to the diminution in the self-induction in the primary circuit produced by this rod, whose conductivity is so good that it absorbs practically no heat.

Another point which is brought out by these experiments is the great conductivity of rarefied gases when no electrodes are used as compared with that of electrolytes. An exhausted bulb will produce as much effect on the discharge in A as the same bulb filled with a solution of an electrolyte containing about a hundred thousand times as many molecules of electrolyte. The molecular conductivity of rarefied gases when the electromotive intensity is very great and when no electrodes are used must be thus enormously greater than that of electrolytes.

Bulbs filled with rarefied gas used in the way I have described serve as galvanometers, by which we can estimate roughly the relative intensity of the currents flowing through the primary coils which encircle them. Used for this purpose, I have found them very useful in some experiments on which I am at present engaged on the distribution of very rapidly alternating currents among a network of conductors.

I have much pleasure, in conclusion, in thanking my assistant, Mr. E. Everett, who has done the whole of the very large amount of glass-blowing required for these experiments, and has rendered very efficient help in other parts of the work. My thanks are also due to Mr. A. T. Bartlett, B.A., for the assistance he has given on several occasions.

DESCRIPTION OF THE STANDARD VOLT AND AMPERE-METER USED AT THE FERRY WORKS, THAMES DITTON.*

BY CAPTAIN H. R. SANKEY AND F. V. ANDERSEN.

(Continued from page 70.)

4. Measuring Volts.

The apparatus for this purpose is shown on Fig. 1 (with connections in black) in a diagrammatic form. It consists of a D'Arsonval galvanometer, G_2, with a resistance, R_V, in series, and a rheostat, P, connected with the difference of potential leads—for instance, with the terminals of a dynamo.

The scale of the galvanometer has a second graduation constructed in accordance with a calibration, so as to have its divisions proportional to the corresponding currents through the galvanometer. This proportional scale is divided from 0 to 175 volts, and unit deflection on the volt scale is produced by a current through the galvanometer of 1 micro-ampere.

In measuring potential differences smaller than 1 volt, the rheostat P is not used, but the potential difference to be measured is directly connected into the circuit of G_2.

When measuring potential differences higher than 1 volt, the potential difference to be measured is connected across the rheostat P, of which a small section—"a" on Fig. 1—is connected with the circuit of G_2. This section "a" is so adjusted as to be exactly a hundredth part of the total resistance of P + the dynamo leads, which sum is = 250 ohms.

The ratio $\frac{a}{P + \text{leads}}$ is called the potentiometer factor.

When it is required to measure high voltages, a second and even a third rheostat, P_1 and P_2, each of 250 ohms, can be joined in series with P, and the potentiometer factor altering from a hundredth to two hundredth or three hundredth. Further alterations can, of course, be made in the voltmeter constant by varying the resistance R, as in the case of the ammeter.

The potentiometer factor is evidently independent of the temperature of the rheostat P. The temperature correction required in R_V is simply ·023 per cent. of R_V* + ·388 per cent. of G per degree Centigrade of variation. It will be seen that for the ordinary ranges the resistance of the galvanometer—about 435 ohms—is very small compared with R_V, and that, therefore, the errors in the measurements due to unavoidable small errors in the estimation of the temperature of R_V are quite insignificant. If

k = current through G per unit deflection on volt scale;
K = volts to be measured ,, ,, ,,
f = potentiometer factor;
G = resistance of galvanometer;
R_V = ,, in series with galvanometer;

then, for any deflection, D, on the volt scale,

$$(G + R)\, k\, D = f\, K\, D;$$
$$\therefore R = f_1 k K - G \quad . \quad . \quad . \quad . \quad (3)$$

In the present case,

k = 1 micro-ampere = 1×10^{-6} amperes;
G = 435 ohms (legal) at standard temperature;

therefore the resistance R to be used in series with the galvanometer to obtain different voltmeter constants = $f\, K \times 10^6 - 435$.

Table II. contains in column 1, the constants used with the instrument; in column 2, the corresponding values of R_V; and in 3, the value of the temperature correction in ohms, per degree Centigrade deviation from the standard temperature—17° C.

Table II.

Voltmeter constant, K.	R_V in legal ohms.	Correction per ° C. from 17° C.	Remarks.
0·0005	60	1·68	Direct connection.
0·001	555	1·80	
0·005	4,517	2·71	
0·01	9,469	3·85	
0·05	60	1·68	1 potentiometer rheostat
0·1	555	1·80	
0·5	4,517	2·71	
1	9,469	3·85	
2	,,	,,	2 ditto in series.
3	,,	,,	3 ,, ,,
4	12,773	4·61	3 ,, ,,

NOTE.—The resistance R_V by formula 3 is of course in true ohms; the amounts of R_V in Table II. are given in legal ohms, as the resistance boxes available were adjusted in legal ohms. For the purpose of reduction, 1 legal ohm has been taken = ·9977 ohm. The figures have further been reduced about 1·2 per cent. to balance a change of constant.

The strongest current which at any time will pass through the galvanometer circuit is the current which deflects to the end of the scale, or ·000175 ampere. The heating caused by this current in the galvanometer, as well as in the resistance-box, coils is quite inappreciable, and the galvanometer may therefore be left "on" for any length of time.

For everyday work the scale is used, the readings being well within 3 per cent. of error. For more accurate work, however, readings are taken at intervals, and the mean reading is afterwards calibrated against the standard cell as follows:—The determination of the potential difference corresponding to the given mean deflection being made by substituting for it an E.M.F. equal to that of the standard cell, shunting the galvanometer, and adjusting the resistance in series with it till the deflection is produced.

* Paper read before the Institution of Electrical Engineers.

* The coils being made of platinoid wire.

Then, if

E = the potential difference required ;
r = total resistance of potentiometer rheostat plus dynamo leads ;
$r\,a$ = section of this resistance tapped to galvanometer ;
$R_V + G$ = resistance of galvanometer circuit when G is used as voltmeter ;
$R_1 + G$ = resistance of galvanometer circuit when standard cell is used ;
m = multiplying power of shunt when standard cell is used ;
e = E.M.F. of standard cell at the given temperature ;

we have,
$$E = \frac{r}{r\,a}\,\frac{R_V + G}{m\,R_1 + G}\,e. \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

5. Measuring Resistances.

With the addition of a few Leclanché cells, with key, and a short-circuit key for galvanometer, the apparatus contains everything required for making Wheatstone bridge tests with good accuracy.

Very small resistances, such as the resistance of a dynamo armature or of a brush contact, are, however, taken by passing a current through the resistance, reading simultaneously the amperes passing through it and the potential difference at its ends. The numerous constants given for the ammeter and voltmeter on Tables I. and II. enable the tester to get accurate measurements on this plan with current differing in strength according to circumstances. The following is an example of a test of the resistance of an armature with two different currents :—

Amperes through armature.	Volts between brushes.	Resistance. in ohms
25·9	·203	·00784
47·1	·370	·00786

Insulation resistance can be measured in the ordinary way—by the deflections—by means of the E.M.F. of any available dynamo ; and as the value of the current through the galvanometer is read direct, the time usually spent in determining the constant of the galvanometer is saved.

Example :

The E.M.F. of a dynamo running excited without load was measured on the voltmeter galvanometer G_2, in the ordinary way, and found = 103 volts. The circuit from this dynamo was then opened, and again closed by joining one end of it to the shaft, the other end to the commutator of an armature the insulation of which was to be tested. The insulating material of the dynamo armature thus formed part of the circuit, which was made direct through G_2—the potentiometer rheostat having been disconnected. The reading on the volt scale was now 89·5 ; *i.e.*, a current of 89·5 micro-amperes was passing through the circuit.

The total resistance of the circuit was, therefore,

$$\frac{103 \times 10^6}{89{\cdot}5}\,\omega = 1{\cdot}151 \text{ megohms},$$

including the insulation resistance + a few hundred ohms resistance of G_2 and leads.

The experiment was made in the manner described because there did not happen to be at the moment two sets of leads available, so one galvanometer (G_2) had to be used. Otherwise the best way is to measure the volts by G_2 and the current by G_1.

6. Description and Calibration of Instruments.

Galvanometers.—As has been already mentioned, these are of the D'Arsonval type, which was chosen on account of its dead-beatness, and more particularly its independence of variations in the surrounding magnetic field. It is hardly too much to say that a system such as that described in this Paper depends on the D'Arsonval galvanometer for its existence. The galvanometers are mounted on a stone supported on thick india-rubber rings, an arrangement which has been found to a large extent to stop the transmission of vibrations. The scales are at a distance of 5ft. from the galvanometers.

(To be continued.)

THE CRYSTAL PALACE ELECTRICAL EXHIBITION.

A meeting of the Honorary Council of Advice in connection with this Exhibition was held at the Mansion House on Wednesday, under the presidency of the Lord Mayor, to receive a report from the Directors of the Crystal Palace Company as to the progress of the Exhibition, and to consider the best method of making the Exhibition of scientific value.

The LORD MAYOR opened the proceedings by calling upon Mr. G. T. Rait to address the meeting.

Mr. RAIT stated that, in the absence of the Hon. D. G. Monson, the Chairman of the Crystal Palace Company, he had to thank the Lord Mayor for presiding, and for giving them the opportunity of meeting at the Mansion House. He had also to say, on behalf of his Company, how much indebted they were to the Electrical Section of the London Chamber of Commerce, and also to the Honorary Council, for attending that meeting. He then asked Mr. Gardner, the secretary of the Crystal Palace Company, to read the report of the Directors to the Honorary Council and Committee.

Mr. GARDNER read the report, in the course of which the Directors stated that the Crystal Palace, having been intimately associated with the early introduction in this country of what may be called the modern application of electricity, they deemed the time ripe for a second Exhibition. During the past ten years enormous strides had been made in electrical engineering ; but probably the great majority of the British public were still unaware of the vast extensions and present developments of this important branch of science. The machinery of the former Exhibition was comparatively small and inefficient. The forthcoming Exhibition would afford a favourable opportunity for conducting test experiments ; and it was believed that tests undertaken at the present time by a public body would be of great service both to the scientific world and to the industry at large. The Exhibition of 1881 was recognised as the pioneer of electrical engineering in this country, and the Directors confidently believe that the Exhibition of 1892 will be equally memorable. The forthcoming Exhibition, which would be opened on January 1, 1892, would be divided into three great divisions, each of which would be subdivided into sections. First division, heavy electrical engineering (electric lighting) : second division, utilisation of electric currents other than for lighting ; third division, generation and utilisation of electric current from primary batteries, in connection with telephony, telegraphy, and other purposes. The space available for the above purposes, though large, has, the Directors state, been over applied for, and every section of the industry will be well represented. Invitations are to be issued to public bodies throughout the United Kingdom to visit the Exhibition.

The LORD MAYOR stated that the report which they had just heard read was extremely interesting. They had his best wishes, as representing the City of London, that it would be a success, and anything that he could do towards that end would be most readily done.

Mr. W. H. PREECE stated that there was no doubt that during the past ten years very great progress had been made, both scientifically and practically, in applying electricity not only to the purposes of lighting, but also to the utilisation of waste, and to the development of heat in places where the mode of producing heat now was most objectionable. Most of these matters, as well as many others too numerous to mention, would be dealt with at the forthcoming Exhibition. The practical application of electricity to the wants and purposes of mankind seemed to be only limited by the inventive genius of those who were engaged in studying this wonderful science. The demand, too, for the application of electricity seemed to be almost unlimited. Such an Exhibition would take the place very much of an educational establishment ; and they would also have the means by which those who were experts could study the progress which had been made in other countries. He believed that the Exhibition at the Crystal Palace in 1881 was called "International." The word "international" had, however, very much dropped out of fashion. Such Exhibitions were becoming far more national than international. The forthcoming Exhibition at the Crystal Palace would be national, and would be a means by which English engineers would have an opportunity of making comparisons, without being affected by prohibitive tariffs. They had to show as far as they could the development of electricity. The report referred to certain tests that would be made, and he was asked to propose the appointment of a committee of experts whose duty it would be to perform the functions of juries. He concluded by proposing the appointment of the following gentlemen as a committee of experts :—Prof. W. Grylls Adams, Prof. W. E. Ayrton, Major P. Cardew, Prof. W. Crookes, Sir James N. Douglass, Mr. W. B. Esson, Prof. D. E. Hughes, Mr. Gisbert Kapp, Prof. A. B. W. Kennedy, Mr. W. H. Preece, Prof. J. Perry, and Prof. Silvanus Thompson.

The DUKE OF MARLBOROUGH, in seconding the motion, said there was no doubt that the formation of the proposed committee would help to give the Exhibition an instructive character. From his point of view as Chairman of an Electric Light Company, or from what he would call the commercial side of the question, he would not go quite so far as Mr. Preece in saying that they had arrived at the time when they could produce the same amount of effective light at the same price as gas ; but he had no doubt that the time was rapidly approaching when they would do so. Since the Exhibition at the Crystal Palace in 1881 such great progress had been made in the industry that they had now got it on to a safe commercial basis. In the City of London they were interested in one of the largest problems in connection with electric lighting. The City of London had not only given the franchise to a public company for the lighting of the houses and offices in this important centre, but had also been public-spirited enough to give the Company the street lighting. A great duty and responsibility devolved on the Company, which had undertaken this work, and he hoped the Company would be able to make its start in private installation work by having the pleasure of lighting the Mansion House. Undoubtedly a great deal of work would have to be done before the City could be properly lighted by electricity. The streets were so full of gas and water pipes and post-office cables, as well as a great many other things of the kind, that it was extremely difficult to know beforehand whether they would find room for putting the cables down which were required for the purpose. It was in view of this difficulty that it had been resolved to adopt a system of light which entailed the use of converters, which, however, would not be in the houses of the consumers, but under the charge of the generating company. To

Digitized by Google

carry out the work properly must, however, be a matter of time. The City Commissioners of Sewers had really shown great indulgence to the new Company; but he would take that opportunity of asking the City authorities and the public to be indulgent with the enterprise, and not to press it forward too hurriedly. If time were given to them he had not the least doubt that the public would come in with capital, and that the City of London would be one of the standing instances of the early successes of electric lighting. The company which had the City lighting also had a free field—no competition—while in other cases the Board of Trade had thought it right to give the lighting to two companies—one on the continuous and the other on the alternating system. He doubted the wisdom of this course. He was glad to see that the report which had been read to them embraced so many points in the electrical industry. As Mr. Preece had said, it covered the widest field; and the fact was that there was no limit to which the application of this science was not capable.

The resolution was unanimously agreed to.

Mr. RAIT then cordially thanked the Lord Mayor for presiding. He expressed a hope that the Exhibition might be opened punctually on the 1st of January, and that the Lord Mayor might honour them on that occasion with his presence. The Crystal Palace Company would do all in its power to make the Exhibition a success in every way; and with the assistance of the able committee of experts which had been appointed, success seemed assured.

The LORD MAYOR, in reply, repeated that it had afforded him the greatest pleasure to receive them at the Mansion House. He would do all in his power to further the movement, to which he again wished every success, and he would use every effort to attend the opening of the Exhibition next January.

The proceedings then terminated.

LEGAL INTELLIGENCE.

Hampton and Sons v. London Electric Supply Corporation (Limited).

In the Court of Appeal on Wednesday, the case of Hampton and Sons v. London Electric Supply Corporation came before the Master of the Rolls, Lord Justice Lopes, and Lord Justice Kay, in the form of an appeal from the judgment entered by the Lord Chief Justice in favour of the defendants.

Mr. Jelf, Q.C., and Mr. Lee Roberts appeared for the plaintiffs in support of the appeal; while Mr. Moulton, Q.C., Mr. Pyke, and Mr. Hanhan, opposed it on behalf of the defendants.

Mr. JELF, in supporting the appeal, said this was an action brought by Messrs. Hampton and Sons, of 8, 9, and 10, Pall Mall East, S.W., against the defendants, to recover damages for an alleged breach of contract, by which the defendants agreed to supply them (plaintiffs) with the electric light. The case was tried before the Lord Chief Justice and a special jury, who found that there was a contract by the defendants to supply the plaintiff with electric current up to 600 lights on the terms embodied in the application form; that the defendants had broken the contract, and that the plaintiffs had suffered damages to the extent of £175 beyond the sum which had been paid into Court, without any admission as to liability. Notwithstanding these findings, the Lord Chief Justice entered judgment for the defendants. The learned judge appeared to have taken the view, that although the parties intended that there should be a contract for the supply of electric current, and that although the plaintiffs acted on the faith of the contract, and expended a large sum of money in preparing their premises for it; yet it was impossible to put one's finger upon anything that constituted an actual contract upon the part of the defendants to supply electric current for any time. The learned counsel submitted that there was clear evidence of a contract between the plaintiffs and the defendants. The letters contained ample evidence that the defendants accepted the plaintiffs' application. After having accepted the plaintiffs' application and allowed the plaintiffs to go to great expense in preparing their premises for the light, the defendants said they could not supply the plaintiffs' premises from their Grosvenor Station owing to the demand upon that station.

Mr. MOULTON: It was tremendously black weather.

The MASTER OF THE ROLLS: Yes. I remember something very black about the supply from the Grosvenor.

Mr. MOULTON, on behalf of the defendants, said that plaintiffs desired to be supplied with the electric light and the defendants were anxious to supply it, but there was no contract. There was clearly no contract to supply the current for any definite time, and in such a case as the present that meant there was no contract in respect of which anybody could sue.

The MASTER of the ROLLS said he agreed with the Lord Chief Justice that there was no contract for the supply of the electric current which would bind the defendants. There was no contract to supply either for a specified time or for a reasonable time; and a contract to supply for as long as the person supplying chose was equivalent to no contract at all, and no person could sue in respect of any breach of it.

Lord Justices LOPES and KAY concurred.

Appeal dismissed accordingly, with costs.

Chase v. Henley's Telegraph Works Company (Limited).

In the Queen's Bench Division on Monday, Mr. Justice Mathew and Mr. Justice Charles, sitting as a Divisional Court, had before them the case of Chase v. Henley's Telegraph Works Company, which was an appeal by the defendant Company from the decision of Mr. Justice Jeune at Chambers, refusing to set aside the judgment entered by the plaintiff.

Mr. RAM (with whom was Mr. Reid, Q.C.,) said the plaintiff originally brought two actions against the defendant Company to recover sums of money in respect of commission earned under an agreement. In the first action the plaintiff claimed £2,100, to be paid partly in cash and partly in shares of the International Cable Company; and in the second he claimed £1,117 in cash. The actions were consolidated, and subsequently an agreement was drawn up, embodying terms for settling them. Under the agreement it was arranged that the claim should be paid half in cash and half in shares of the International Cable Company. It was further provided that if the terms of the agreement were not carried out by the defendant Company, judgment should be entered for the plaintiff. On the execution of the agreement of compromise the defendant Company paid all the cash due by them; but on the 26th of July, 1890, an order was made to wind-up the International Cable Company; and the defendant Company were prevented from handing over shares in that Company in accordance with the agreement. On 17th of April, 1891, judgment was obtained by the plaintiff for £1,608. 10s., thus treating the shares in the International Cable Company which had not been transferred as cash. Mr. Justice Jeune had refused to set that judgment aside, and the defendant Company now appealed. He (the learned counsel) submitted that the plaintiff might have obtained a transfer of the shares at any time for what they would have been worth, and that, therefore, the judgment ought not to stand.

Their Lordships, without calling upon Mr. Bankes for the plaintiff, dismissed the appeal with costs.

Lane Fox v. Kensington and Knightsbridge Electric Lighting Company.

Mr. Justice Romer, in the Chancery Division, heard on Saturday last the case of Lane Fox v. Kensington and Knightsbridge Electric Lighting Company. The action is one for alleged infringement of patent. The case now came before the Court on questions as to the sufficiency of interrogatories relating to the novelty of the invention and other matters. Mr. Wallace, who appeared in support of the application, obtained in one instance a fuller reply with respect to a question of the novelty of the patent, but failed on other points. His Lordship decided that the costs shall be the costs of the other side in any event.

Nourse v. Boland.

On Friday last, in the Queen's Bench Division of the High Court of Justice, before Mr. Justice Wills, sitting without a jury, the case of Nourse v. Boland came on for hearing. Mr. Asquith, Q.C., M.P., and Mr. Gore were counsel for the plaintiff, while the defendant was represented by Mr. Bigham, Q.C., and Mr. Lewis Coward.

Mr. ASQUITH, in opening the case, said the action was brought to recover remuneration for work done by plaintiff, as he alleged, at the request of the defendant, in connection with procuring the sale of certain electrical patents from an American company, to which they originally belonged, to an English company which was ultimately floated. Both plaintiff and defendant were American gentlemen; Mr. Nourse, who had independent means, having been resident in this country for some years; defendant only came over to England from time to time in connection with this matter. There was a company in Boston called the Thomson-Houston Electric Welding Company, and it possessed a patent for working a process under which electricity was applied to the welding of metals. In 1889 the American company despatched a Mr. Lewis and the defendant to England for the purpose of effecting a sale of their patents to a company or syndicate. The plaintiff was first put into communication with Mr. Lewis, and he took him to a firm of financiers in the City of the name of Russell and Co. In the course of conversation Messrs. Russell and Co. said they would not feel inclined to entertain the proposal of forming a company until the validity of the patents and their practicability had been submitted to a practical expert, and he suggested that Mr. Matheson should be called on to make a report. Several further interviews took place, after which Mr. Lewis went away, whereupon defendant arrived, and he continued the negotiations. In consequence of a letter from Lewis the plaintiff, on September 8, 1889, went to the Hotel Metropole and saw defendant. He arranged to take Boland to Messrs. Russell and Co. to continue the negotiations which Lewis had left incomplete. Many interviews took place, plaintiff assisting at all, and he suggested that it would be desirable, if a company was to be brought out, that some experimental works should be erected in the first instance, so that a practical test of the patents should be undertaken, and people be able to verify for themselves the value of the invention. Messrs. Russell agreed to get together £20,000 for the purpose of constructing experimental works, and if successful they agreed to form a company with a capital of £250,000, for which the patents were to be sold. After some time, however, the defendant introduced the matter to the City of London Contract Corporation, and they agreed to float a company which was to take over the patents. Although plaintiff was disappointed at the negotiations with Messrs. Russell and Co. falling through, he continued to render defendant assistance in the changed aspect of affairs. A forge was erected at Hoxton, and plaintiff went about among friends in the City, many of whom he hoped would subscribe to the capital of the Company. In fact, he devoted the greater part of the business hours of a year to the work, and in promoting the success of the undertaking. The Company was formed in August last under the name of the Electric Welding Company (Limited), with a capital of £460,000; and the question for his lordship was whether plaintiff was entitled to any remuneration for the services he undoubtedly rendered defendant, and for which he had been led to expect payment.

Mr. THORNDIKE NOURSE, the plaintiff, then went into the box, and stated that his business was to bring sellers into communication with possible buyers.

Digitized by Google

In cross-examination the plaintiff said he had been asked to get his friends to subscribe to the capital of the Company, and he was to have 5 per cent. on the amounts so subscribed. Afterwards, however, he was told that his proceedings were likely to interfere with a Mr. O'Hagan, who was acting in the matter, and he was asked by the defendant to withdraw his efforts. If he had been allowed to carry out his work to its completion he would have been satisfied with the 5 per cent. he had been promised; but his complaint was that the business was taken out of his hands, and he was prevented from getting the money he had been expecting to earn.

Certain interrogatories and other documents having been put in, this concluded plaintiff's case.

Without addressing the Court Mr. Coward called the defendant, Mr. W. A. Boland, who, in the course of his examination, said when plaintiff called on him he offered to introduce him to Messrs. Russell and Co., but he did not accept the offer, as he did not wish to interfere with what Mr. Lewis was doing, as Lewis was coming back to London. Later on he saw Nourse again and told him he had arranged the sale of the patents, and there was nothing he could do in the way of negotiations. He added that he had dismissed Russell and Co. from the matter, as they had declined to come forward with any money.

Mr. O'HAGAN, the Chairman of the City of London Contract Corporation, and Mr. MATHESON having been called,

Mr. JUSTICE WILLS said he was of opinion the plaintiff's case had been disposed of; and gave judgment for the defendant with costs.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *November* 7, 1891.

Electric Heaters.—An effort is being made just now to put divers sorts of electrical heating apparatus on the market. There are at present several very excellent forms of electric heaters for small work, and at least one of these—the Burton heater—is finding its way into a fair amount of use on electric cars. In point of economy it does not compare very favourably with coal stoves, but in comfort to the passengers and convenience it is unsurpassed. About 2 H.P. is required to heat an ordinary 16 or 18-foot car in cold weather.

Electric Lighting Effects.—One of the prettiest applications of electric lighting that New York has witnessed for many a month was to be seen last Monday evening at the Madison-square garden. A very beautiful flower show is now in progress there, and the interior of the building is illuminated not by the regular incandescent lamps ranged along the roof, but by festoons of Chinese lanterns strung in every direction radially and across the building. These are many hundreds in number, and each contains an incandescent lamp, except where the festoons cross, and at these points a gigantic Chinese lantern holds an arc lamp. But the finest effect, perhaps, was seen outside. The tower of the building had just been completed, and the weather vane—a colossal statue of Diana—had just been placed in position. The statue stands on a gigantic crescent, which blazed with 200 incandescent lamps. Two huge search lights were turned on the statue and on the upper portion of the tower, bringing it out into bold relief against the almost black sky, while immediately under the crescent from time to time a similar light was turned on at full force. In addition, the tower itself was brilliantly illuminated with electric lamps. The next evening the search light on the tower of the garden was used to signal, by prearranged code, the result of the New York State election to the cities immediately surrounding New York.

High-Pressure Electric Transmission.—Rapid transit seems to be making particularly little progress. The plans presented, as I have stated before, are rather too elaborate to invite capital, and very little is now heard of any definite efforts to hasten the work. Electrical rapid transit is likely to come in Chicago long before New York; indeed, it will not be surprising if the World's Columbian Exposition saw some very striking examples of it. It is somewhat doubtful if the plan which has more than once been suggested of transmitting power from Niagara will be carried out, as the chief of the Electrical Department does not at the present time see where the funds for such an experiment are to come from. But America is likely soon to have one or more good examples of the use of very high voltages in power transmission. At least, plant of this description is likely to be erected in California before long. Success may be safely counted upon, for the climatic conditions in that State are far more favourable than those under which the Lauffen-Frankfort transmission was carried out.

NEW YORK, *November* 18, 1891.

The Microphone "Interference" Case.— It has been rumoured within the past few days that a decision in one of the Bell Telephone Company's interference cases had resulted in the issue of a patent which would practically give that greedy corporation a monopoly of the business for a good many years to come through the medium of a broad claim on the carbon transmitter. The Bell Telephone Company, more than any other organisation in the history of the United States Patent Office, has abused the privileges offered by Patent Office procedure, keeping interferences alive and patents withheld, purely and simply for the purpose of obtaining—contrary to the spirit of the patent laws and public policy—patents so dated as to prolong its atrociously abused monopoly. The rumour seems at present writing to be groundless, probably being merely an attempt to influence the price of telephone stock; but there is great danger that such a patent may be obtained by the Telephone Company, unless so strong a pressure of public opinion is brought to bear upon the Commissioner of Patents as to check any action on the ground of fraudulent intent on the part of the litigants, a conclusion that might well be made, considering that the Bell Telephone Company has for years owned both sides of all the important telephone interferences.

The Overhead Wire Question in New York.—The perennial war on the overhead electric wires in New York is threatening again, and indeed the Board of Electrical Control has recently taken steps to have a considerable number of overhead wires taken down and put into the conduits. Meanwhile the subway facilities are as bad as ever, and the old wrangle between the Subway Company and the Electric Light Companies is as yet undecided.

Storage Battery Traction.—The recent report of the Commission appointed by the United States Government to look into the construction of subways in Washington will probably have the effect of bringing further pressure to bear against overhead wires in this country. The trolly system of electric railways is thoroughly prevented from making any extensions in Washington by the strong sentiment against overhead conductors; and the result has been the establishment of an experimental line of storage cars, under the superintendence of Mr. C. A. Mailloux, which is reported to be doing very fair work. Speaking of storage batteries, the Waddell-Entz car, equipped with alkaline zincate batteries, has been recently making a series of very successful experimental runs. A large number of the cells have now been manufactured, and tests seem to show that they are capable of doing very excellent work. The question of durability, of course, is a difficult one to decide, as the type has not been manufactured long enough to permit of very accurate judgment. The inventors, however, say that the results thus far obtained have been very encouraging, and appear to show that in spite of the low voltage of the cells they are admirably adapted for street car service.

Forthcoming Edison Alternate-Current System.—The Edison Company is reported to be getting ready to put its alternating system on the market. It will be remembered that something over a year ago a suit was brought by Ganz and Co. against the Edison Company on the ground that the patents which the latter had undertaken to work in the United States had been simply quashed, and that nothing has been done towards developing them. If rumour speaks correctly, the first of next year will see the Edison Company exploiting an alternating-current system; and it is expected that this will possess the peculiarity of utilising the three-wire system and 110-volts, somewhat perhaps after the manner suggested by H. Ward Leonard in his Paper read before the National Electric Light Association at Montreal. Details of the Edison apparatus are not at hand. It is understood to be not widely different in general character from the systems usually employed in this country; and as it has been worked out largely by Mr. A. E. Kennelly it is only fair to assume that it will prove successful.

CORRESPONDENCE.

THE THEORY OF THE WIMSHURST MACHINE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Having read with considerable interest a letter on the above subject by M. G. Pellissier in your last issue, and also an article proposing a new theory by the same author in your issue of October 2nd, I should like in the first place to say a few words in reply to his criticisms on the theory of the Wimshurst machine, which I give in my book on Influence Machines; and, in the second place, to offer a few criticisms on the theory which M. Pellissier proposes.

M. Pellissier says in his letter that the theory which I have given is "no other than that of Prof. Thompson." A more careful comparison will show that this conclusion is erroneous. Prof. Thompson's latest theory of the Wimshurst machine, as far as I know, is given in his Paper on the Influence Machine read before the Institution of Electrical Engineers (*The Electrician*, Vol. XXI., June 8, 15, and 22; *Journal* of the Inst. Elec. Eng., Vol. XVII., p. 613). The assumption with which he starts is that "some of the metal carriers are charged positively, others negatively." It is not stated whether the positive and negative carriers follow each other in any particular order; but farther on we find that it is assumed that the carrier on the back plate, which at any instant lies opposite the upper end of the neutralising rod of the front plate, has always a positive charge. Such a state of things would, of course, soon impart to the plates of the machine the *final* distribution of electricity which is known to exist when the machine is active; but it appears to be an explanation of how the Wimshurst machine is excited by the influence of a foreign electrified body held opposite one of the brushes, rather than a theory of how the machine excites *itself* with the plates in any condition (electrically) at starting.

In my theory, I start with the assumption that one-half of one of the discs has a small positive charge, and the other half a small negative charge, and from this I show that by the action of the machine a similar distribution at right angles will be produced on the second plate. Then, owing to the fact that the inductive action of all the similarly charged carriers on one plate is focussed on the touched carrier on the other plate, a greater charge is produced on the touched carrier than on any one of the inducing carriers. This increase of charge follows the same law as the increase of money at compound interest. A charge of electricity invested, as it were, in a carrier of the inducing plate, produces (with the help of the other adjacent carriers) in the touched plate a charge equal to the original charge invested, plus more or less interest, according as there are more or less sectors on the machine and according to the distance between the plates, &c. The increased charge on the second carrier now becomes the principal for producing a further increased charge on the first plate, and so on, according to the well-known formula for compound interest.

This law of the increase of the charges I have explained in the theory given in my book, though not in much detail, as it had already been explained with reference to previous machines. M. Pellissier also makes this very clear in his article (*The Electrician*, Vol. XXVII., October 2nd, p. 604). Prof. Thompson does not mention this law of increase in his Paper already referred to; in fact, one would think that he had overlooked it in his theory of the Wimshurst machine, as he assumes in his illustration that six positive units in an inducing carrier will produce six negative units in a touched carrier, conditions under which it is easy to see that there would be no increase of the charges on the carriers.

My theory was not intended to show how the *final* distribution arises from the *primitive* distribution, for the reason that I considered that to be impossible in the present state of our experimental knowledge, and by no means simple even with sufficient experimental data. All that I intended to explain was that the *final* distribution was stable and tended under proper conditions to increase indefinitely in intensity,

Nor do I think that M. Pellissier in his article in the *Journal de Physique* of which you publish the translation in your issue of October 2nd last, has succeeded in establishing the nature of the primitive distribution, or demonstrated the nature of the process by which the *primitive* distribution passes by the action of the machine into the *final* distribution. M. Pellissier assumes that one of sectors A (*see* Figure, *The Electrician*, Vol. XXVII., October 2nd, p. 604) of the back plate opposite the upper end of the neutralising rod of the front plate has a small positive charge. No explanation is given in his Paper why this particular sector should have a positive charge. But assuming that this *primitive* charge exists he claims to show that the *final* distribution will result by the action of the machine. Now the new element which M. Pellissier claims to have introduced into his theory of the Wimshurst machine is the inductive action of a charged sector upon adjacent sectors on the *same* plate. It has not been usual to take this into account, and, in fact, in most machines it would be much less than the inductive action of the charged sectors on the *other* plate. But the mistake made by M. Pellissier is in assuming that this side action on adjacent sectors only acts towards one side only, that is on the side where it helps the final distribution; its action towards the other side, namely on the sector A_7, will produce a negative charge where a positive charge is required and retard the *final* distribution. Indeed, to follow with rigid accuracy the development of the charges by the machine from any given primitive distribution of charges, we must calculate the effect on each sector when in contact with a brush by taking into consideration the amount of charge, distance, &c., of every other carrier on both plates. Is this possible, or is it worth the labour?

I fear that I have written you at much too great a length on a subject which is at present merely of theoretical interest; but the influence machine may any day become of the greatest practical interest, when electricians will discover that it is now, as regards efficiency, in about the same condition as the dynamo was when Wheatstone and Siemens read their historical Papers before the Royal Society.—I am, &c.,

November 23, 1891. J. GRAY.

ELECTRIC LIGHT CABLES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read with interest your leading article under the above heading, which appeared in your issue of the 20th inst., and ask your permission to make some remarks thereon in the columns of your journal. I will notice first the remark you make concerning the insulation resistance of cables below 150 megohms, which, you say, makers, in their lists, "discreetly pass by in silence." The reason of their doing this is that such cables are insulated with lappings of pure indiarubber, and no test *under water* can be guaranteed for cables insulated only with pure indiarubber tape. Those cables having the insulation resistance stated are tested under water after at least 24 hours' immersion. The tests are usually taken with a mirror galvanometer, and the voltage seldom less than 400, and, of course, often very much higher. This minimum test of 400 volts is necessary to ascertain whether the cable is perfectly manufactured or not. Those who have had experience in cable factories are aware that for a given thickness of insulation the megohm test is a true indication of the quality of the material, and the workmanship. The buyer satisfies himself of the thickness of the insulation by the inspection of samples. We are aware that price lists sometimes give the diameter of the cables; but the buyer who knows his business does not take this as giving an indication of the thickness of the insulating material, as the cable can be made large by tapes or thick braiding yarns, which, of course, are considerably less expensive than the insulating material proper.

The course adopted by my Company in preparing its price lists may be of interest to you. In the first instance the thickness of the insulating material is decided upon, sufficient being given to ensure what we consider necessary for mechanical protection; then the degrees of quality of material we apply fixes the insulation resistance in megohms. For example, we consider that a 7/15 cable for house-wiring should have an insulation ·057in. thick, making the diameter *outside the insulation* ·330in. We then use this size for our three classes usually

Digitized by Google

employed for house-wiring. The diameters of the cable are thus the same, but the insulation resistance varies according to the quality of the rubber used; class "N," at £90 per mile, giving 300 megohms per mile; class "G," at £95, giving 750 megohms per mile; and class "A," at £102, giving 2,000 megohms per mile. The small increase in the price, compared with the increase in the insulation resistance, is partly accounted for by the fact that the specific gravity of the best quality vulcanising rubber is less than that of inferior qualities, and therefore a less weight of the former than of the latter is required for a given diameter. The experienced cable manufacturer knows exactly the minimum insulation resistance his various qualities of vulcanising rubber will give, as raw Para indiarubber, unlike gutta-percha and many other insulating materials, does not vary, the raw Para of to-day is the same as that imported years ago.

It is perhaps to be regretted that I cannot write of this matter without there being a suspicion of advertising the wares of my Company, but I feel that a letter dealing with a subject of such importance is more worthy of attention when written over the signature of the writer.—I am, &c.,

G. Sutton,
Manager W. T. Henley's Telegraph Works Co., Limited.

27, Martin's-lane, Cannon-street, E.C.,
November 25, 1891.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

Now Ready.—"The Electrician" Primers (38 in all. Vol. I., 20; Vol. II., 18), in two volumes. Price per volume 2s. paper covers, 2s. 6d. cloth; post free, 2s. 2d. and 2s. 9d. respectively. Single copies, 3d.; post free, 3½d. Prospectus on application to the Publisher.

Tenders Invited.—The London County Council invites tenders for the electric lighting of the central offices of the Council in Spring-gardens. Tenders must be sent in by 10 a.m. on December 15th. Further particulars appear in our advertisement columns.

——— The trustees of the town and harbour of Whitehaven invite offers from companies or persons for the transfer of their statutory powers under the Whitehaven Electric Lighting Order, 1891. Tenders must reach Mr. John Collins, the secretary to the Trust, Town Hall, Whitehaven, not later than 12 noon on December 12th.

The Chicago Exhibition, 1893.—It is announced that the Royal Commission for this Exhibition are now prepared to receive applications for space in the British Section. Applications are to be made upon forms which may be obtained at the offices of the Society of Arts, London, where all further information can be obtained.

Mr. C. Polyblank.—This gentleman informs us that he has resigned his position as mechanical and electrical engineer to the Swansea Harbour Trust, and has opened an office at 47, Wind-street, Swansea.

A Staple Driver.—In a Trade Note on p. 727 of Vol. XXVII., we ventured to offer some criticisms on the staple-driver which was there described. So far from being offended, as sometimes happens when manufacturers expect nothing but praise or a bald description of their goods, Messrs. Woodhouse and Rawson United (Limited) have modified the tool in accordance with our suggestions, and have sent us a sample of the improved form. We have given it a trial on several yards of bell wire, and find that it works very well. The plunger is hollowed out at the end, so that the staple cannot be driven too far.

Mr. W. S. Sargeant.—This gentleman, who is the late manager of the electric and steam launch works, Strand-on-the-Green, Chiswick, has severed his connection, by mutual arrangement, with Messrs. Woodhouse and Rawson United (Limited). He is now carrying on business as an electric and steam launch builder, and laying down plant and machinery for the construction of electric motors for water propulsion and compound surface condensing engines at Strand-on-the-Green, Chiswick.

The Electric Light in British Guiana.—A correspondent writes us that considerable progress is being made in the electric lighting of British Guiana, and that at present the Company lighting Georgetown have a Thomson-Houston A 35 650-light alternator and a Thomson-Houston E 12 arc machine for nine 1,200 c.p. lights. About 500 16 c.p. lamps are installed, and also a circuit of forty 25 c.p. series lamps for street lighting. The machines are driven by a Macintosh-Seymour engine of 100 H.P. The Company have a contract with the Town Council of Georgetown to commence on January 1st next with 190 series street incandescence lamps of 25 c.p. each, and 18 arcs of 1,200 c.p.; and for this purpose a Thomson-Houston A 35 and a Thomson-Houston K 12 arc machine are being put down. The last-mentioned installation will be driven by another Macintosh-Seymour engine of 130 H.P., and the first Babcock Wilcox boiler ever introduced into British Guiana is now being put down.

Electric Light Cables and Wires.—We have received the new price-list of Henley's Telegraph Works Company, giving the usual particulars of their well-known cables. Conductivity of 100 per cent. of "pure copper" is offered. The list is dated October, 1891.

——— The Fowler-Waring Cables Company send us a price-list of their manufactures. It bears no number or date other than 1891. The accumulation of price-lists in most offices is so great that it is very important that the latest list should be easily recognised. A brief description of the method and materials employed in the manufacture of these cables is given. Directions are given for jointing and insulating lead-covered cables, but they assume a good deal of previous knowledge on the part of the reader. It is necessary to seal up the ends of these cables to prevent access of moisture to the insulation. Two methods are described: one is merely a cap of Chatterton; the other consists in cutting away an inch and a-half of lead, and thoroughly insulating the part bared to a level with the lead, and wrapping over all stout waterproof tape. The end piece of lead is then well insulated from the rest, and may be soldered to the copper conductor, completely protecting the insulation from the action of wet.

——— The weights and resistances of the stranded conductors of the Fowler-Waring list appear to be taken from actual observation. The sectional area of a mile of 7/16 is about three per cent. greater than seven times the area of a mile of No. 16. The weight is a little over two per cent. greater. The resistance is greater than one-seventh that of a single wire, but is less than the inverse ratio of the weights, as might be expected (*The Electrician*, Vol. XXVI., p. 412). It is not clear how the Henley Company manage to give such a liberal weight of copper; their 7/16 is five per cent. heavier than the single wire, and the resistance only differs by one per cent. from the inverse ratio of the weight. The extra weight may be due to a shorter lay.

Messrs. Poole and White (Limited).—This firm report that they are busy in all departments, and that a very heavy demand is made upon them for the Poole and White Holder, which has been so favourably received by the trade.

Messrs. Carrick and Ritchie.—This firm forward us illustrated particulars of the "Waverley" Turbine, and inform us that they have recently fitted up a turbine working with a fall of 650ft., the highest fall (so far as they are aware) in Great Britain. There is, no doubt, a great development taking place in the application of water power for electrical purposes, and Messrs. Carrick and Ritchie are making a number of turbines to meet this demand. Accompanying the printed particulars sent are illustrations showing the turbine fixed and at work under varying conditions.

The Mills Compound High-Pressure Sectional Steam Boiler.—We have received printed illustrated particulars from the manufacturers of these boilers, which claim to give high economy, duty, and efficiency. The feature of this boiler which distinguishes it from most water-tube boilers, is the water-cased furnace, which is practically a small Cornish or single-flue boiler within a water-tube boiler. The connections in the steam and water drums are so arranged that the nipple connection can be examined and cleaned from the outside: the inclined water tubes are expanded at each end into vertical heaters having large well areas, each containing one row of tubes. These boilers are suspended on wrought-iron girders and columns, and are free to expand and contract without undue strain. It is claimed that the boilers can be erected, completed, and tested before being enclosed within the brick-work. Tabulated particulars accompany the printed matter issued by the Company, giving the comparative tests of the boiler.

A New Tramway Brake.—The Portstewart Steam Tramway Company have had some of their tramcars fitted with the Pari Emergency Brake, to act automatically in the event of a car breaking away from the engine, and also for application by hand when required. The brake was some time ago tested by Major-General Hutchinson, R.E., and approved by the Board of Trade, the trials made to test the brake having proved satisfactory.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

October 12, 1891.

17,324. G. J. PARFITT and G. J. T. J. PARFITT. Keynsham. Improved method of electric lighting in series and apparatus therefor.

October 13, 1891.

17,399. E. T. GILLILAND. Glasgow. Improvements in dynamo-electric machines.

17,402. A. MARR. Manchester. Improvements in telephonic transmitters.

17,406. J. T. TODMAN and A. E. ANGOLD. London. Improvements in electric arc lamps.

17,426. E. ANDREOLI. London. Generating ozone by electricity.

17,430. D. M. LAMB. London. Electric batteries.

17,434. F. BRYAN AND WOODHOUSE and RAWSON UNITED (LIMITED), London. Improvements relating to dynamo-electric machines.

14,454. R. THRELFALL, London. Improvements in electric conductors for the distribution of electric currents, and in conduits therefor.

17,459. G. H. JONES, London. Improvements in and relating to electric bells and indicators.

17,470. R. J. BOTT, London. Improvements in the holders of incandescent electric lamps.

October 15, 1891.

17,581. F. J. MORGAN and W. R. JAMES. Blaina. An anti-binding wire insulator for suspending or carrying electrical wires.

17,614. A. SHIELS. Glasgow. Improvements in couplings for electric wires.

17,631. A. S. ELMORE. London. Improvements in the process and apparatus for electrolytic manufacture of tubes, pans, and other bodies of circular form.

17,652. H. H. LAKE. London. Improvements in carbons for electric arc-lamps. (The Thomson-Houston International Electric Company, United States).

17,655. G. D. BURTON, A. H. EDDY, and G. T. BRIGGS. London. Improvements relating to the heating of metals by electricity and to machines therefor.

October 16, 1891.

17,706. F. H. NALDER, H. NALDER, C. W. S. CRAWLEY, and A. SOAMES. London. An improved form of voltmeter.

17,707. F. H. NALDER, H. NALDER, C. W. S. CRAWLEY, and A. SOAMES. London. An improved form of voltmeter.

17,719. A. H. BYNG. London. An improved electric or galvanic battery, and its adaptation to brushes and other articles.

17,726. A. P. MORISON, J. HIRSHFELD, and W. WRIGHT. New York. Improvements in portable electric lamps and battery therefor.

17,731. O. LINDERS. London. Improvements in electric motors.

17,732. O. LINDERS. London. Improvements relating to electric motors.

17,733. O. LINDERS. London. Improvements in electric machines for drilling, boring, grinding, and the like.

17,734. O. LINDERS. London. Improvements in electric switches.

October 17, 1891.

17,758. THE MINING AND GENERAL ELECTRIC LAMP COMPANY (LIMITED), and J. T. NIBLETT. London. Improvements in elements for secondary batteries.

17,808. A. J. BOULT. London. Improvements in electrical accumulators or storage batteries (H. L. H. Maugras, France).

17,809. T. G. H. NICHOLSON. Liverpool. Improvements in or applicable to magnetic compasses or other instruments in which dials or movable indices are employed.

17,818. L. PYKE and E. S. HARRIS. London. Improvements in or connected with electric transformers or induction apparatus.

17,823. C. W. L. BARBER. Lowestoft. An application of the electric light to a gun for the purpose of illuminating the object aimed at.

17,831. W. J. B. BANKS. London. An improved compound for insulating, covering, moulding, and analogous purposes.

October 19, 1891.

17,836. R. N. LUCAS. London. Improvements in and relating to electric meters.

17,849. J. A. LEA, J. F. LEA and A. H. LEA. Shrewsbury. Improvements in electric light fittings.

17,852. F. J. PALMER. Dawlish. Improvements in telephone apparatus, or in telephonic instruments, and in coin-controlled mechanism for use with or in connection with same.

17,855. W. T. PRESSLAND. London. Improvements in wall plugs for electric lighting.

October 20, 1891.

17,906. J. J. APSEY. London. Improvements in electric belts and fastenings therefor, which are also applicable to corsets, bags, boots and shoes, and the like.

17,907. A. A. C. SWINTON. London. Improvements in electric signalling.

17,916. J. SHEPHERD and T. S. WATNEY. Leeds. Improvements in dynamo-

17,965. P. A. NEWTON. London. An improved mode of and apparatus for transmitting and recording electrically autographic messages, signals, and markings. (E. Gray, United States).

17,971. J. W. and C. F. DU LANEY. London. Improvements in electric clock-winders.

17,974. A. ALLEN. London. Improvements in insulation for electric conductors. (C. T. Snedekor, United States).

17,994. B. SCHEITHAUER. London. Improvements in and relating to electric batteries.

18,002. J. LA BURT and W. H. AGRICOLA. London. Improvements in railway electric block signal systems.

October 21, 1891.

18,011. A WHALLEY. Helsby. Improvements in telephone switchboards.

18,019. J. H. HINDLE. Manchester. An improved ceiling-rose or ceiling-plate for suspending electric lamps.

18,044. A. H. BROADBENT. Liverpool. Coin-freed apparatus for telephones.

18,059. F. W. GOLBY. London. Electrical counting apparatus. (G. Goulier, France).

18,080. J. H. GREENWOOD. London. Improvements in fire alarm telegraphs.

18,093. E. J. ELKINSTON. London. New or improved automatic circuit closing device for electric fire-alarms. (The Compañia Electricista contra Incendios, Spain).

October 22, 1891.

18,097. C. N. SOUTHER. London. Improvements in galvanic batteries. [Date applied for under Patents Act 1883, Sec. 103, March 23, 1891 being date of application in United States.]

18,143. H. A. MAYOR, W. A. COULSON and S. MAYOR. Glasgow. Improvements in the method of mounting storage battery plates.

18,162. H. C. GOVER. London. Improvements in electrical lamp and other fittings.

18,179. A. GRAY and R. HAMMOND. London. Improvements in or relating to the coupling of dynamo-electric machines in parallel.

SPECIFICATIONS PUBLISHED.

1890.

7,035. LEA. Electricity meters. (Price 8d.)

17,394. VIALET-CHABRAND. Making or breaking electric circuit. (Price 11d.)

15,575. DE MERITENS. Galvanic batteries. (Price 8d.)

COMPANIES' MEETINGS.

Swan United Electric Light Company (Limited).

The ninth ordinary general meeting of the shareholders of this Company was held on Tuesday last at the Cannon-street Hotel; Mr. J. S. Forbes presiding.

The ASSISTANT-SECRETARY (Mr. H. Charles Gover) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen, I will in the ordinary course of things proceed now to make a few remarks upon the report and accounts; and probably the most convenient method will be to deal with the figures first before entering upon more general questions. The material thing in these yearly accounts is to ascertain the result of the working of the year, and that will be found in the profit and loss account, which is in fact is the trading account for that period. It is very short and very simple, and very easily comprehended. If you will kindly follow me through the debtor side, and then through the creditor side of the accounts, I think you will be able to appreciate very shortly and clearly the position of the undertaking as a going concern for the past twelve months. The first entry you see is the amount of stock on October 1, 1890, brought forward, £11,124; then comes the item "purchases," £11,723, which means the material, and, in some cases, the finished articles necessary to carry on our business. Then come the costs of the general administration of the Company—"salaries, Directors' fees, rent, office expenses, income-tax, general and law charges," £3,379. Then there are "wages and expenses at the factory," £5,107—that is over and above the mere cost of purchases and materials, being the cost of turning these into a saleable commodity. After that appears a small amount written down, £392, and "sales of ledger reserve," £300, against the probabili

Digitized by Google

of bad debt. Then there is the "balance" of £39,038. On the opposite side of the account our business "sales, less commissions and allowances," stand at £15,348; interest and transfer fees, £1,290; dividend on shares in La Compagnie Générale des Lampes Incandescentes, less tax, £1,178; and dividends on shares in the Edison and Swan United Electric Light Company (Limited), £34,799. The stock of materials and lamps on hand with which we closed the year stands at £18,449. Well, dealing with the creditor side of the account, as representing what may be called a solid asset, and dealing with the other side as representing the cost of that asset, you see what the balance is—£39,038. You will at once observe that a very large part of that balance, representing profit, is derived from the investment of your money in the Edison and Swan United Electric Light Company (Limited), £34,799. I think I have said enough about that until I come to some details which I will deal with later on. I now take you to the balance sheet. There you see the state of the share capital. There are so many shares fully paid, and so many only partially paid—standing at £5 in the former case and £3. 10s. in the latter, and showing that the total capital is £375,071; we have an item for forfeited shares, £3,530, being the amount paid by people who failed to pay up the calls on their shares, which, after due notice was given to the parties holding them, were forfeited. Then there are sundry creditors £4,642, and the balance from previous account £8,451, because last year we did not divide up to the hilt, and carried forward that amount. This makes the sum available for dealing with £47,490. Well, in this Company as in other companies which have an annual balance-sheet and an annual distribution of profits, when they are trading on what is something like solid principles there is what is called a provisional or interim dividend. We have had it for a year or two, and on account of the first half of this year we paid £11,104 in dividend. That deducted from the £47,490, leaves £36,386 now to be dealt with to day. On the other side of the account you get a very simple statement of the position of the Company. You will see "By cost of patent rights, &c.," represented by shares in Edison and Swan United Electric Light Company, Limited, with £208,478 paid; shares in La Compagnie Générale des Lampes Incandescentes with £30,489 8s. 3d, paid; patents held by the Company for Germany, &c., as per last balance sheet, making a total of £330,837," which is the amount we have written down for the cost of all these; and if you cast your eye to the other side of the balance-sheet you will see that the capital paid up is £375,000 odd. There is, I see, an additional item of expenditure of £1,612, subject to re-adjustment between the companies, which brings the figures up to £332,449. Then comes the "outlay on factories, plant, &c., less depreciation," £1,570, because you cannot establish a factory calculated to turn out any considerable number of lamps for anything like £1,500; and that amount is low because for some years we have written off 20 per cent. out of revenue on account of the money expended in that way. "Sundry debtors" stand at £6,545, which exceeds the corresponding entry on the other side of the account, "sundry creditors," by nearly £2,000. "Stock in hand" is £18,449; "investment in Prussian Consols," £5,120; "investment in New Two and Three Quarters per Cent. Consolidated Stock," £29,004; and "cash on deposit and in hand," £26,490. Well, now, first of all, what are you going to do with the balance of £36,386? What the Directors recommend you to do they set forth in the body of the report, and that is that the dividend for the year should be at the rate of 11 per cent., which will absorb £28,376. 6s. 11d., in addition to the £11,104 distributed as interim dividend, and leave £8,010 to be carried forward for the benefit of the current year, which you will see is within £450 of the amount we brought forward the year before. This seems to be a recommendation entirely justified by the state of the balance-sheet; and I think you will agree with me that in the position of the Company it is prudent not to divide up to the hilt. Therefore, if the year's business has resulted in this, that you can pay 11 per cent. and carry forward into the current account about the same balance as you did last year, it is not so very bad, particularly when you take into consideration one of the unrealised items of the profit and loss account, and that is the stock on September 30, 1891, £18,449. I have had occasion to explain before—and, perhaps, I had better explain again, because these meetings are held only once a year, and because we know by the transfer lists our proprietors change, and some of them, at all events, are not yet familiar with the details or principles upon which this business has to be conducted—I wish to explain that it is quite certain that these lamp companies cannot conduct their business satisfactorily without having on hand a large amount of stock. The lamps, although they are generally described as being of 16 or 8 c.p. or some other denominative quality, in fact greatly vary in many particulars, and outside, what you may call the ruck of the business, there are a great many lamps made to special order, which involve a great many types and subdivisions of stock. That is a disadvantage in one sense and an advantage in another. A great business cannot be done without a large stock, which means a large amount of money locked up. That may, by and by, turn out to be an advantage to those big companies which have had the start for a term of years and have made a reputation and a *clientèle*, and which, from the fact of their being able to turn out very large numbers of lamps, can do so at a price at which a small man could not possibly live. That stock of £18,000 odd is made up very largely of lamps—in round numbers to about £11,000. Of course, if we met to day and were to say, "We have come to the end of our business," and were to realise our assets, you might ask: "What is the stock worth—how many lamps are saleable and at what price?" As you have credited the account with the actual cost you would realise a moderate profit on the sales, which is, of course, what you would do, it would be all that money to the good. Therefore, what I am dealing with now is an ascertained, humanly speaking, absolutely safe profit of 11 per cent., with £8,000 odd carried forward from the previous year, with a contingent value lying dormant, the benefit of which you will get in future years. That is the basis of the whole thing. I do not propose to go into the details of these various figures except by way of answering any questions, which I take the liberty of inviting shareholders to put to me as representing the Board. Now, I will come to something a little more general. The most satisfactory part of this report is the paragraph which tells you that the decision of the Supreme Court at Leipsic, in the patent cases which certain companies with very long names brought against this Company and their agents, has now been given in favour of the Company. This is a matter of great moment. The question in dispute was exactly the same as that which was in dispute in England when the wisdom, I think, of some of the gentlemen sitting at this table induced the Edison Company and the Swan Company to put their forces together, instead of cutting each other's throats. Oddly enough, in Germany, the Edison Company, or those representing it, and those representing the Swan Company, have not been able to follow so wise an example, with the result that they have been in litigation now for several years, the Swan Company having been brought to book by the Edison Company as infringers of its patents. We never raised that question in this country. It is not for want of trying on our part that that state of things continues in Germany. We have long tried to persuade our friends there that what has turned out to be so good in England might also turn out to be of advantage in Germany; but they have not seen it. The result is that we have now been declared in our final appeal, after protracted proceedings which are equal to anything that we know in connection with the Law Courts in England, as illustrating the law's delay, to have succeeded; that is to say, the Swan lamp has been declared to be no infringement of the Edison patents. And the result is that we are now free to go on our way without being denounced in any way as infringers, without our customers being threatened with proceedings, and without our being threatened with damages in the event of our being found guilty. And then you see that places the German business in a very different position from what it was in before; and what the Board say is, "The Directors are now engaged in the consideration of the best way to take advantage of the favourable position thus created in Germany." It is the difference between working in freedom and working in chains. Although under the German law, the penalties upon people who are wrongdoers in the dark and without knowledge are generally very light, when they have been once warned by legal notice that their policy is wrong they are pretty heavily salted. Though we went on making Swan lamps we had always the fear before us of final damages; and during the last year or two, having learned a little by litigation, and being careful lest some abstruse point might turn against us, we did not push our business as we could have done, and as we shall certainly push it now. The next paragraph is about our little investment in Paris. The same conflict is going on there as to the patents, and I suppose about the time these run out the same decision will be come to. The Company in Paris is not doing so very well, for the reason that they are in litigation with everybody that can make lamps and send them into France, and there is what is called a "cutting of rates" going on. But it is still possible that that state of things may terminate sooner or later, and I suppose the French companies will come to some understanding among themselves, because, of course, there is no particular object in men giving their brains and money to manufacture lamps and sell them at a price which leaves no profit. People may do so for a time, but they ultimately get tired of it. That brings me really to the end of the report; but I will make this observation. The Swan Company have got now into a peculiar position. We have divested ourselves of any care or trouble about the working of our British patents, and we did that by virtue of £208,478 of capital held in the Edison and Swan Company. I do not know whether honourable proprietors appreciate that that Company is doing very well, and that in all probability in the future it will be, at all events, tolerably well off. It may be like other companies; they have got to face the state of things which will arise when the protected period runs out. That they have foreseen. They have laid their plans and shaped their policy upon this: that they must make hay while the sun shines—that is to say, they must make the best lamp, get the best *clientèle*, and establish the best reputation, and at the end of that time they must take their chance with other people. But they will then find themselves in a position to make as good a lamp as anybody else, and probably better; they will find themselves in a position with a great number of persons who, having a knowledge of the article, will not be easily tempted to change it very readily for another; and with the ease of capital at their command they will be able to produce these lamps at a price as low as, if not lower, than other people can; and, therefore, will be able to sell at the minimum of profit. In fact, it means this: a small profit on a large number, instead of a large profit on a small number; and you participate in that proceeding to the extent of £208,478. You are the largest shareholders in the Edison and Swan Company. As to our lamp business in France, that is represented by £30,489. The French Company are very powerful, and the French people—we are inclined to think so—are not so methodical or business-like as we are; they are more scientific and logical, but not quite so practical; but they will be able to take care of themselves. Let us hope so. This German business, which may be a more or less important factor, in proportion to its magnitude, was exceedingly troublesome to the Directors in former years. The lawsuits are now settled, and, therefore, it is just for consideration whether it is worth while administering that portion of the business as a separate Company with separate machinery for the purpose. When the litigation was over here, we thought it would be a prudent thing to consider at all events whether the Edison and Swan Company in England might not absorb upon some fair and reasonable terms the outlying business and assets generally of the Swan Company. They have got a considerable sum of money and other things at command, which could be utilised by the Edison and Swan just as well as by the Swan Company as a separate undertaking. We shall probably desire, at some early date, to consult the proprietors on details. The Edison and Swan Company are a united body, but although they are united they consist of two parts; and although they have an identity of interest, on the question of the buying and selling of a new business they might not have. We have

Digitized by Google

imported into our happy family of Directors members from the Edison and Swan Company, who represent themselves largely and their co-partners. We have gentlemen connected with our Board who hold largely for themselves and represent the interest of the Swan Company, and we thought it prudent that two gentlemen on either side should meet and consider this question of fusing the existing Swan Company, or, rather, taking over the assets and outstanding business not already provided for upon some terms which will be acceptable to the proprietors of both companies. It will not take very long to come to some reasonable conclusion upon it. I thought that the proprietors should know that. It will, perhaps, save somebody asking questions. We think that the time has gone by when it is necessary to carry on the Swan Company as a separate undertaking merely for the sake of conducting the German business, when it could be equally well and perhaps more profitably done by the Edison and Swan Company. I hope the principle will commend itself to the proprietors. Unless I am challenged upon any figures as to which any proprietor is in doubt, I will now move:—

"That the report and accounts for the year ended September 30, 1891, be received and adopted."

Mr. F. R. LEYLAND seconded the motion.

A SHAREHOLDER asked how long the German patent lasted.

The CHAIRMAN: The German patent is not in question. All that has been determined in Germany is that the Swan patent is not an infringement of the Edison. We have never got so far as to establish the Swan as a patent, and I don't suppose we ever shall.

The motion was carried unanimously.

The CHAIRMAN, continuing, said: There is one thing which I have found in my experience: it is much easier to put and carry than most things—that is, the distribution of a dividend. The dividend that we are to propose is so complex that it bothers me. The cause of that complexity is, however, very simple when you do understand it, like that egg of Columbus. The shares are divided into £5 fully paid, and partially paid £3. 10s.; and the character of the bargain was this, that up to 5 per cent. the £5 was to receive its 5s., and the £3. 10s. was to receive its 3s. 6d. or 1s. in the pound. After that it was to be equal per share, which complicates the calculation; in fact, it makes a difference of about £1,770 in the calculation. If the fully-paid shareholders were entitled to receive 5 per cent. upon their paid-up capital, the amount of money to disburse would be that amount more than it is. Therefore, relatively, they get a little less dividend. I now move:—

"That in addition to the interim dividend at the rate of 6 per cent. per annum for the six months ended March 31, 1891, already distributed, a dividend at the rate of 6 per cent. per annum be and is hereby declared on the shares of the Company for the half-year ended September 30, 1891 (making 6 per cent. for the year), and of 5 per cent. for the twelve months ended September 30, 1891, free of income-tax, to be distributed in accordance with the provisions of Clause 77 of the Articles of Association."

Mr. LEYLAND seconded the motion, which was carried unanimously.

The CHAIRMAN: The next thing is the re election of the retiring Director. I apprehend there will be no question about that; Mr. Swan's name is so well known, his services to this Company have been so considerable, and he has so identified the name of Swan with the Swan United Electric Light Company (Limited), that he has, as a matter of course, quite apart from considerations of fitness, and a large holding in the Company, and, as everybody knows, great inventive and business capacity, a claim upon your sympathy.

Mr. J. C. STEVENSON, M.P., claimed the privilege of proposing the resolution before the meeting, having been long connected with the Company, and having been Chairman of the Newcastle Board, with which Mr. Swan's attention had first been taken up. He begged therefore with much pleasure to propose:—

"That Mr. J. W. Swan be and is hereby re-elected a Director of the Company."

Mr. C. TOOTH seconded the motion, which was passed unanimously.

Mr. SWAN having briefly expressed his acknowledgments,

The auditors, Messrs. Welton Jones and Co. were unanimously re-appointed.

A vote of thanks was afterwards accorded the Chairman and Directors.

The CHAIRMAN briefly responded, remarking that if they had not had the essential conditions of success—the support of those whom they represented—they could not have got so successfully through the many difficulties which they had had to encounter.

The proceedings then terminated.

Blackpool Electric Tramway Company (Limited).

The annual meeting of this Company was held on Saturday at the Tyldesley-road Schools, Blackpool, Mr. R. Horsfall (Chairman of Directors) presiding.

The CHAIRMAN, in moving the adoption of the report published in our last issue, said he thought the results of the past year had been most satisfactory, both as regarded their finances, the condition of their works, and, in fact, everything else. The only item showing an increase was that of wages, which increase was occasioned, to a great extent, by the sand nuisance at the south end of the town. This inconvenience was largely increasing every year, and during the last twelve months they had had a good deal of trouble with it.

The motion, having been seconded, was unanimously adopted.

The retiring Directors, Messrs. Horsfall, Bickerstaffe, and Broadbent (Managing Director), having been elected,

Mr. HOYLE proposed a vote of thanks to the Directors for their services; and, referring to the 18th clause of the Towns Improvement Bill, dealing with powers over tramways, &c., expressed the opinion that the Corporation already had powers enough, and he trusted they would oppose the Corporation having any more powers touching their (the Tramway Company's) property.

The motion was carried unanimously.

Mr. J. P. Taylor was re elected auditor to the Company.

This concluded the ordinary business, but the meeting afterwards had a private sitting to consider the Towns Improvement Bill as it affected the Company.

NEW COMPANIES, STATUTORY RETURNS, &c.

ALMERIA AND ALHAMILLA RAILWAY COMPANY (LIMITED).—This Company was registered on the 18th November, 1891, with a capital of £100,000, in £5 shares, by Messrs. Ingledew, Ince and Colt, St. Benet Chambers, Fenchurch-street, E.C. The objects are:—To purchase the concession and works of the railway at Sierra Alhamilla to the dock of Almeria, in Spain; to carry on the business of a railway company generally, to acquire the right to use or manufacture and put up telephones, telegraphs or other electrical apparatus, whether for lighting, signalling or telegraph purposes, and for other purposes. Registered office: 108, Bishopsgate-street, E.C.

DE WINTON AND CO. (LIMITED).—This Company was registered on November 20, 1891, with a capital of £20,000, in £10 shares, by T. T. Hull, 22, Chancery-lane, W.C. The objects are:—To acquire and carry on the business of ironfounders, engineers, manufacturers of marine and other engines, carried on by J. P. de Winton and O. Thomas, at Carnarvon and elsewhere. The first Directors are J. P. de Winton, O. Thomas, and R. Parry-Jones. Solicitor: C. H. Rees, Carnarvon.

ELECTRICAL FINANCE CORPORATION (LIMITED).—This Company was registered on November 18, 1891, with a capital of £100,000, divided into 19,800 ordinary and 200 founders' shares of £5 each, by C. G. Baker, 22, Great George-street, Westminster, S.W. The objects are:—To construct, contract for, establish, and carry on, or to finance and provide capital for companies having for their objects the supply of electric light, power, and heat, and the production, transmission, storage, and use by any means and for any purpose of light, heat, electric, magnetic, or other force. The subscribers are:—

The number of Directors is not to be less than three nor more than seven, the first to be appointed by the above subscribers. Qualification, £250; remuneration, £100 per annum each, and £100 additional for the chairman.

NEWMANS (LIMITED).—This Company was registered on the 19th November, 1891, with a capital of, £50,000, in £10 shares, by Bonner, Wright, Thompson and Co., Ingram House, 165, Fenchurch-street, E.C. The objects are:—To acquire, develop the resources of and turn to account land, mines and real or personal property of every description: to construct, maintain, improve, develop, and work any electric power, heat, and light supply works, telephone works, &c.

PEACOCK'S PATENT STEEL GRIP, LOCK, NUT, AND FISH BOLT SYNDICATE (LIMITED).—This Company was registered on the 18th November, 1891, with a capital of £30,000, in £1 shares, by Waterlow and Sons (Limited), 85, London-wall, E.C. The objects are to acquire the benefit of a certain existing invention, particulars of which are not given, and to carry on the business of iron founders, mechanical and electrical engineers, tool makers, brass founders, metal workers, &c.

STAR TUBE COMPANY (LATE TAUNTON AND HAYWARD, LIMITED).—This Company was registered on November 19, 1891, with a capital of £50,000, in £5 shares, by Jordan and Sons, 120, Chancery-lane, W.C. The objects are:—To acquire and take over as a going concern the business of Taunton, Delmard, Lane, and Company (Limited), and to carry on the business of mechanical, chemical, electrical, scientific and general engineers, designers and constructors, founders, manufacturers, workers of and dealers in iron, steel, brass and other metals, &c. The number of Directors is not to be less than three nor more than seven, the first to be appointed by the signatories to the Memorandum and Articles of Association.

SUTTON'S PROCESS SYNDICATE (LIMITED).—This Company was registered on November 18, 1891, with a capital of £15,000, in £1 shares, by Gerrish and Foster, 26, College-street, E.C. Objects:—To acquire from H. Sutton certain letters patent for "An improved process for converting a photographic image on a gelatine surface into a relief or intaglio printing surface," and to carry on the businesses of inventors, photographers, chemists, plate and metal manufacturers, printers, electrotypers, engravers, electricians, telegraphists or photo-telegraphists, &c.

SWANSEA CHEMICAL COMPANY (LIMITED).—This Company was registered on November 19, 1891, with a capital of £30,000, in £100 shares, by Witherby and Co., Newman's-court, Cornhill, E.C. The objects are to carry on the business of chemical manufacturers, including the manufacture and sale of sulphuric acid, hydrochloric acid, oxalic acid, salt cake, artificial manures and any other chemicals or chemical products.

WILSON AND LONGBOTTOM (LIMITED).—This Company was registered on November 19, 1891, with a capital of £16,000, in £10 shares, by Waterlow and Sons (Limited), London-wall, E.C. The objects are:—To acquire and carry on the business of Wilson and Longbottom, of the Nelson Foundry, Barnsley, and to carry on the business of mechanical engineers, machine and engineering tool makers, boiler makers, iron and brass founders, millwrights, metal workers, steel converters, colliery owners, metallurgists, and manufacturing chemists.

CROMPTON ELECTRIC SUPPLY COMPANY OF AUSTRALIA (LIMITED).—The annual return of this Company, made up to November 10, 1891, was filed on the 17th following The nominal capital is £50,000, divided into 9,500 A and 500 B shares of £5 each; 3,115 A and 500 B shares have been taken up, the 500 B shares being issued as fully paid. The A shares have had the full amount called, and £13,765 has been paid, leaving £1,810 unpaid. Messrs. Crompton and Co. (Limited), of Mansion House-buildings, E.C., hold 993 A shares. Registered office: Mansion House-buildings, Queen Victoria-street, London, E.C.

ELECTRIC DATE AND TIME STAMP COMPANY (LIMITED).—The annual return of this Company, made up to August 11, 1891, was filed on November 17, 1891. The Company was registered on April 13, 1888, to acquire and develop the invention of an electro-mechanical date and time stamp, and now has a capital of £121,000, divided into 100,000 original and 21,000 new shares of £1 each; 6,893 original and 21,000 new shares have been taken up, and upon 2,393 of the original shares the full amount has been called, and, with the exception of £122. 10s., paid. The remaining 4,500 original and 21,000 new shares have been issued as fully paid. Registered office: New Broad-street House, New Broad-street, London, E.C.

ELECTRICAL INVENTIONS COMPANY (LIMITED).—The statutory return of this Company, made up to the 6th November, 1891, was filed on the 21st following. The Company was registered on the 18th September, 1890, to acquire, develop, and deal in patents for electrical inventions, and had a capital of £35,000, in £1 shares. Seven shares only are taken up, upon which nothing has been called, the original signatories being the only shareholders. No agreements for the taking over of any concessions, businesses, patents, &c., have been filed, and no office registered.

MONTE VIDEO TELEPHONE COMPANY (LIMITED).—The annual return of this Company, made up to the 13th November, 1891, was filed on the 17th following. The Company, which was registered on the 31st July, 1888, has a nominal capital of £220.000, divided into 29,000 preference and 15,000 ordinary shares of £5 each. 28,000 preference and 15,000 ordinary shares have been taken up, of which 3,000 preference and 3,000 ordinary were issued as fully paid. Upon the remaining 25,000 preference and 12,000 ordinary the full amounts have been called and paid, realising £185,000. Only 1,000 out of the 44,000 shares are at present unissued. Registered office: 25, Abchurch-lane, E.C.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts of this Company for the week ended November 22nd amounted to £792; aggregate receipts for half-year to date, £15,157.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The Stock Exchange Committee have ordered ordinary shares Nos. 40,001 to 70,152 to be quoted in the Official List.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—Notice is given that 312 £5 per Cent. Mortgage Debentures of this Company have been drawn for payment at par on January 1st next at Messrs. Barclay, Bevan and Co.'s, 54, Lombard-street, E.C. Further particulars will be found in our advertisement columns.

ELECTRICAL UNDERGROUND RAILWAY BETWEEN FINSBURY PARK AND THE CITY.—Parliamentary notice has been given by a new company of its intention to promote a Bill in the next Session for powers to construct an electrical underground railway, commencing by a junction with the Great Northern Railway at Finsbury Park, and terminating in the City about the centre of Finsbury Pavement. Powers will also be sought to run into and use the Finsbury Park Station of the Great Northern Railway Company.

HALIFAX AND BERMUDAS CABLE COMPANY (LIMITED).—The following has been issued to the holders of the Four and a-Half per Cent. Debentures of the Halifax and Bermudas Cable Company (Limited), 33, Old Broad-street, London, E.C.:—"It has been brought to the notice of the trustees of the £120,000 Four and a-Half per Cent. Debentures of this Company that the investments to be made on behalf of the sinking fund for the redemption of the principal sum at the end of 20 years—when the subsidy expires—is so restricted under the trust deed that the result must be a deficiency of about £30,000, while the Company's circumstances would not justify the assumption that that large sum could be provided from other sources. In the interest of the bondholders it is, therefore, imperative to give the trustees larger powers towards this end. At present the choice is limited to such securities as a trustee may select under the Statute, and the yield from such investments would be about 2¾ to 3 per cent. It is now designed to take power to apply the sinking fund to the redemption of the above Four and a-Half per Cent. Bonds, by purchase when the bonds can be got under par, and by drawings when the price is par or above. By this modification the redemption of all the bonds within the term of the subsidy would be practically assured, and the application of the sinking fund to purchases or drawings would further benefit the bondholders by tending to remove the discount at which the bonds now stand. But this modification of the trust deed can only be effected with the consent of the bondholders; and you are, therefore, requested to signify your concurrence in it.—HENRY BRUDENELL BRUCE, C. SEYMOUR GRENFELL, Trustees for the Bondholders."

NATIONAL TELEPHONE COMPANY (LIMITED).—The Stock Exchange Committee have ordered the provisional certificates (partly paid) of a further issue of £250,000 Four and a-Half per Cent. Debenture Stock to be quoted in the Official List.

SPANISH NATIONAL SUBMARINE TELEGRAPH COMPANY (LIMITED).—The numbers are announced of 83 bonds of £100 each of the Six per Cent. Morgage Debentures, to be paid off at par on and after December 31st next at the National Bank of Scotland, Nicholas-lane, E.C.

VENEZUELA TELEPHONE AND ELECTRICAL APPLIANCES COMPANY (LIMITED).—The first ordinary general meeting of this Company was held on Tuesday, when a dividend at the rate of 4 per cent. per annum was declared on the shares of the Company for the half-year ended June 30th.

WATERLOO AND CITY RAILWAY.—Amongst the Parliamentary notices advertised this week is that of the Waterloo and City Subway, or Railway, for which application will be made to Parliament in the ensuing Session for a Bill to enable the Company which will be formed to undertake the construction and maintenance of an underground railway or subway, for the conveyance of passengers, goods, and animals. The railway is to commence in the parish of St. Mary, Lambeth, and to terminate in the parish of St. Mary Woolchurch, in Mansion House-street, E.C., opposite the north-eastern corner of the Mansion House. The gauge to be adopted for the railway will be 4ft. 8½in., and the motive power is to be electricity or cable. The usual powers are asked for, one of which is to empower the Company on the one hand, and any company or person authorised to supply electricity in any district in which any part of this railway or subway will be situated, or the London and South-Western Railway, on the other hand, to enter into or carry into effect

Digitized by Google

agreements with respect to the supply of electricity or electrical energy or power. As usual, plans and sections of the railway proposed to be authorised under the Bill, showing the lines and levels thereof, the lands to be purchased or acquired by compulsion, and a book of reference to such plans, will be deposited for public inspection with the Clerk of the Peace for the County of London, at the Sessions House, Clerkenwell, E.C., and the Clerk of the Peace for the City of London, at the Sessions House, Old Bailey. This, of course, is in addition to the copy of such portion of the plans, sections, &c., as relate to the various localities through which the railway will pass, which will be deposited with the Vestry Clerks of the several parishes. Messrs. Rees and Frere, of 13, Great George-street, Westminster, are the Parliamentary agents for the Bill; and Messrs. Bircham and Co., of 46, Parliament-street, Westminster, are the solicitors.

WOODHOUSE AND RAWSON UNITED (LIMITED).—"It is somewhat strange," says the *Economist* of Nov. 21st, "that at the meeting of the shareholders in this Company, which was held last Friday, no mention was made of the further issue of capital, amounting in all to £165,000, which has since been offered by public advertisement. We have no means of judging to what extent the invitation of the Directors has been successful; but it is not easy to understand why the public should pay a premium of 5s. per share on the new ordinary shares and par for the preference shares and debentures, while the different classes of the Company's securities are quoted at from 20 to 50 per cent. discount. Woodhouse and Rawson United is one of those undertakings in which the proprietors appear to care little about financial stability so long as large dividends are forthcoming. Ostensibly, its business is the manufacture and sale of electrical plant and machinery, and the report recently presented states that the net profit of the supply department had doubled in the year; but the report and the accounts are alike silent as to what amount has been earned by the legitimate operations of the Company, and what by the promotion of Elmore copper."

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 707.—Vol. XXVIII. FRIDAY, DECEMBER 4, 1891. PRICE FOURPENCE. *Annual Subscription (U. K.), 19/6*

NOTES.

The Paper on electrical measurements by Captain Sankey and Mr. Andersen has been somewhat hastily undervalued in some quarters because it contains little if anything that is new. It was, however, an excellent example of a case in which the chief use of the Paper was to provoke discussion; and though this may not have been the object of the authors, such discussion as there was was distinctly useful, and if it had been more general would have been of considerable value. The remarks of Prof. Ayrton, on the other hand, offered an example of misplaced effort. Exactly the same information in the shape of a Paper would have formed an excellent supplement to the one read, since, if time had been allowed, a good discussion might have been raised upon it. That time is required is a consequence of the importance of the subject; it is easy enough to discuss a simple or trivial matter on the spur of the moment.

An important Paper on galvanometers (of which Prof. Ayrton was one of the joint authors) was read before the Physical Society in January, 1890 (*The Electrician*, Vol. XXIV., p. 348). This was similarly very ineffective, provoking as it did only a very superficial discussion, and one quite unworthy of the contribution. That Paper contained the first and the last reference that has been made to a "factor of merit" of galvanometers. It attempted to classify galvanometers into four divisions, depending on the strength of the fields. A factor of merit of a single class of instrument of a certain definite type, and intended for a certain definite purpose, would have some value; and a discussion on such a point would have been very interesting in connection with Capt. Sankey's Paper.

Mr. Siemens may be right in saying that instead of wishing electrical measurement for workshop purposes might partake less of a laboratory character, it should be a matter of congratulation that electrical engineering was becoming so scientific that these methods are well suited to it. But if this should be the case, the requirements and the degree of accuracy in the workshop are so different from those of the laboratory, that there is a good deal to be said about the adaptation of methods and apparatus used in the one, for the special purposes of the other. The time has now come for a thorough discussion on electrical measurements for engineering purposes. Professor Ayrton should write a short Paper, Mr. Crompton another, and some instrument-maker—Mr. Crawley, for example—a third. They should all be printed, including illustrations, and well circulated a few days before reading. On the 17th of last month three Papers were read on the same subject at the Institution of Civil Engineers—much shortened, of course, and were discussed together on two subsequent evenings.

We alluded some weeks ago to the fact that Prof. Ewing was investigating the subject of the iron losses in transformers. His experiments have just been described before the Physical Society of Cambridge, and our readers will find an account of them printed in another column. They appear to settle the question whether the hysteresis losses in a transformer alter with the load to which it is subjected, for they show that these losses are practically constant at all loads, while the transformer is worked under conditions of constant induction or voltage. This has always been the common opinion; but, when the question of its accuracy was once raised, it became necessary to investigate the matter experimentally, as no one could predict the influence of magnetic leakage at different loads. As we have previously pointed out, the great difficulty of the investigation arises in finding a satisfactory method of measuring the iron losses directly; and Prof. Ewing has completely overcome this obstacle in a very ingenious way, so that, in spite of the fact that his transformer is a mere toy in point of size, there seems no reason to doubt the correctness of his result.

Curiously enough, very shortly after Prof. Ewing designed his method of directly measuring the power lost in transformer cores, an entirely different method was published in America. This method is described by Mr. T. Spencer in our excellent contemporary, the New York *Electrical Engineer* for November 11th, and it depends upon the use of a dynamometer of special construction. The instrument possesses two stationary coils and one movable coil. The primary current of the transformer is sent through one of the stationary coils, while the secondary current is sent through the two in series. The winding of the coils has to correspond with that of the transformer tested, and, under these conditions, the reading of the instrument measures the power lost in the iron. The method seems perfect enough theoretically, but it has the great practical defect that, while the coils of the dynamometer must be suitable for the passage of large currents, the actual magnetising effect causing the deflection will be merely that due to a very small current,

Digitized by Google

owing to the opposition of the currents in the two fixed coils As dynamometers are not very sensitive instruments under favourable conditions, the use of them in this manner can hardly prove satisfactory.

The reading of Mr. Robertson's Paper on "Secondary Batteries," or, as he prefers to call them, "reversible batteries," before the Society of Arts on Wednesday evening, brought together a large number of accumulator experts, who were unanimous in congratulating Mr. Robertson on his discovery of the important part played by hydrogen dioxide (H_2O_2) in the economy of the Planté lead-sulphuric acid—lead peroxide cell. In support of the contention that the variations of electromotive force depend on which plate the hydrogen dioxide is formed at, a pretty little experiment was performed, which was, unfortunately, visible only to the respected chairman. A miniature reversible cell, with one of its electrodes in a porous pot, was charged up and connected to a sensitive voltmeter, which showed the abnormally high electromotive force usual in a freshly charged cell. On interchanging the electrodes, taking the peroxide plate out of the liquid rich in dioxide, and placing the plain lead plate there instead, the voltmeter index immediately fell back several points. The importance of H_2O_2 having now been proved, it is for those who want all they have now with half the dead weight to see if they cannot turn the discovery to some practical account.

The Paper on the candle-power of glow lamps, read at the American Academy of Arts and Sciences, and reprinted in our present issue, deals with a matter of great importance; and it is to be regretted that no specimens of English-made lamps were included, not for comparison with other kinds, but because that is the only make with which we are concerned in this country. It is obvious that all such information as is contained in this Paper, and much more, relating to life, is well known to the scientific officials of the Edison-Swan Company, but is jealously guarded as a profound secret. Important as the subject is, there is naturally some apathy about it, because we have no choice but Edison-Swan lamps for ordinary candle-powers, and it is therefore hardly worth while troubling about tests. We have omitted numerous tables and records of tests, because, in the absence of tests of Edison-Swan lamps, the Paper is of only general interest to our English readers.

The correct title of the society to which Mr. Oliver Heaviside alludes at the conclusion of his interesting and useful article this week is the Association for the Improvement of Geometrical Teaching. It was founded, we believe, about ten years ago by a few teachers, who realised that Euclid for children is, as Mr. Heaviside puts it, simply barbarous. Three pamphlets have been published by Messrs. Macmillan and Co.—a syllabus of plane geometry, corresponding to Euclid, Books I. to VI.; another of modern plane geometry; and another of linear dynamics. Messrs. Swan, Sonnenschein and Co. have published an elementary geometrical conics, and there the labours of the Association appear to have stopped. The Association has to struggle against the stubborn conventionalism of the modern schoolmaster, who pleads that he cannot make any change, because of the Universities. After a considerable fight, Mr. Hamblin Smith's common-sense proofs of Euclid's problems were accepted by Cambridge examiners. Small as the visible results of the Association have been, there is a distinct change of feeling taking place with regard to geometry, both as an educational subject and as an implement of scientific work. At present geometry is taught as badly as Greek, even in the best public schools; and the educational value of Greek is in many respects higher than that of Euclid.

An apparatus for transmitting drawings by telegraphy is described in a recent number of *Electricity* of Chicago, and reproductions are given of some attempts to reproduce photographs. Caselli and others worked with more or less success at this problem. Several instruments were shown in operation at the Electrical Exhibition at Paris in 1881, and more than one writing telegraph has been devised. Unfortunately there is no practical demand for anything of the kind. More than a year and a-half ago an apparatus was designed in this country, by which a sketch drawn on tin could not only be transmitted by a single line, but a block of type metal could be engraved at the receiving end, ready for printing, at the rate of about one square inch per minute. Experiments were made, and the results were very promising, but on making inquiries it was found that nobody wanted such a thing—not even the *Daily Graphic* cared to consider it. Like many other scientific novelties, it had no commercial value, and the patent was abandoned. This invention, as well as the writing telegraph, is sure to turn up periodically.

The *Glasgow Herald* of the 28th ult. contains about a column of closely-printed matter, embodying charges of obstructiveness or incompetency on the part of the telegraph authorities in London, who, it seems, have been guilty of rejecting the advice of the writer, or the people whom he represents. He alleges that Glasgow is badly served telegraphically, and roundly appeals to its citizens to see that their grievances are redressed. For one who complains that not only are appeals to "London" of no avail, but that resort to the Press is denied him, this is going rather far. No doubt the "St. Martin's-le-Grand people" will take due note of it. The writer evidently is well informed, but he surprises us rather on one point, though, being a Scotchman, as unquestionably he is, his intense self-sufficiency requires some discounting. He states that under ordinary circumstances all the Glasgow wires are worked by key. If that be the case, no wonder the people in London think Glasgow has wires enough, although the *Glasgow Herald's* prompter does not; and when he goes on to say that on the Wheatstone automatic being resorted to at times of pressure, the London office is not up to the work, the writer rather staggers us, though the statement does not. To read Wheatstone slip is the easiest thing in the world; but to prepare Wheatstone slip for transmission is far from

Digitized by Google

easy; and if, as is admitted, Glasgow rarely practises punching, it is not surprising that when the automatic has to be used, long delays occur through repetitions and inability to decipher in London what has been transmitted from Glasgow, admirable though the operators at that office may be on the key.

Electric Traction at Spezzia.—It is intended to use electricity on a tramway shortly to be constructed by a Belgian Company at Spezzia.

The Telegraph in Mashonaland.—The 200 miles of telegraph line, which have still to be laid to Fort Salisbury, will be completed before the rains begin.

King's College.—A new course of evening electrical engineering lectures and laboratory work will begin at this College on Monday, January 18th.

Cable Communication with Spain.—The Direct Spanish Telegraph Company inform us that direct cable communication with Spain (*via* Bilbao) is restored.

Telegrams to Peru.—Telegrams can now be forwarded to Peru by the routes of the Eastern and Direct Spanish Telegraph Companies, at the rate of 8s. 2d. per word.

The Cadogan Electric Light Company.—This Company will, we understand, commence the new year by adopting the three-wire system with secondary batteries.

Dublin.—Rapid progress, says the *Freeman's Journal*, is being made with the construction of the central station, which is to light this city. It is hoped that the entire work will be completed by next April.

Glasgow.—The Electric Lighting Committee of the Town Council have acquired a site on which the necessary plant will be erected for lighting the central area. The price paid is about £8,000, or between £7 and £8 per square yard.

Brighton.—The Brighton and Hove Electric Light Company give notice of their intention to apply for a Provisional Order authorising them to lay down mains, but not erect overhead wires, in every part of the borough not supplied by the Corporation.

Plauen.—According to the *Elektrotechnischer Anzeiger*, an electric tramway two miles in length is to be built in Plauen. The project, plans for which are being prepared by Messrs. Schuckert and Co., also includes the erection of a central station for lighting.

Interurban Telephony.—A new line has recently been constructed by the Western Counties and South Wales Telephone Company between Tewkesbury and Cheltenham; and during one of the trials of the line some 700 words are said to have been spoken in three minutes.

Appointment Vacant.—The Committee of University College, Nottingham, invite applications for the post of Demonstrator in Electrical Engineering. New engineering schools have been erected, and the appointment should prove an important one. Further particulars are given in our advertisement columns.

A Cable to the Bahamas.—Arrangements have been made for connecting, under subsidy, the Bahama Islands in the West Indies with the general telegraphic system of the world by means of a submarine cable of about 200 miles in length. The cable is being manufactured by Messrs. W. T. Henley and Co., and will be laid in January or February next.

Institution of Electrical Engineers.—A meeting of the students of the Institution was held on Friday, November 27th, when a paper was read on "Electric Mains for the Distribution of Light and Power," by Messrs. Griffin and Minshall. The next meeting will be held on Friday, December 11th, when a paper will be read on "Measuring Instruments," by Mr. W. A. Vignoles.

Nottingham.—Having consulted Dr. J. Hopkinson and Mr. W. H. Preece, the Electric Lighting Committee of the Town Council unanimously recommended that the Town Council should undertake the electric lighting of the borough under their Provisional Order. The Committee add they do not think that for some time to come the supply of electricity to the borough could be made a source of profit.

The Application of Electricity to Mining.—On Saturday afternoon last week the first of a series of seven lectures on this subject was delivered in the Guildhall, Derby, under the auspices of the Midland Counties Branch of the National Association of Colliery Managers and the Derbyshire County Council. The lecturer was Mr. George Fletcher, head master of the Science Department of the Derby Technical College.

Mr. Cyrus Field.—Mr. Field, who has been hovering between life and death since his wife died, was reported to be in a slightly improved condition on Wednesday, having rested well the previous night. He was, however, still in an exceedingly critical state. The latest information by special message is that "he is slightly improved this (Thursday) morning." Mr. Field's daughter is at the present moment dangerously ill, and only a few days ago the firm in which his son, Mr. Edward Field, is a partner, was declared insolvent.

Electric Traction at Croydon.—On Monday afternoon Major-General Hutchinson and Major Cardew visited Croydon for the purpose of inspecting, on behalf of the Board of Trade, the working of an electric car, several similar to which are about to be adopted by the Croydon Tramways Company. The car, which, when empty, weighs 5½ tons, is driven by two motors of 14 H.P. and can attain a maximum speed of 16 miles an hour. A trial trip was made to Thornton-heath, after which the whole of the circuit to North-end, Croydon, was completed without a hitch, and the inspectors expressed themselves as being thoroughly satisfied with the experiment. The car has been built by the Electric Tramcar Syndicate.

The Berliner Microphone.—With reference to the Berliner microphone it may be interesting to note that in November, 1878, a Mr. F. T. J. Haynes, of Taunton, described in the *Somerset County Gazette* a microphonic transmitter very similar to that originally described in the *Scientific American*:—"The instrument consists of a diaphragm made of ferrotype plates fastened in a vertical position. In the centre of the diaphragm a piece of carbon is secured. The base of the carbon is against the back of the diaphragm, and its point rests lightly against another piece of carbon, which is fixed on the top of a brass spring. There is a screw in the rear of the spring for adjusting purposes. This simple instrument, when connected to a telephone and battery, will transmit articulate and other sounds distinctly." Readers who may be interested in the genesis of the microphone will do well to consult Vol. I. of *The Electrician*, 1878.

Sir William Thomson.—On the occasion of the presentation of Sir William Thomson's portrait to the University of Glasgow, on Friday last, Principal Caird concluded his speech as follows:—"May I venture to add that, while we share in the admiration for his varied gifts that is felt for him by those who know him only by reputation, it would have been impossible to have been so long associated with him as I and my colleagues have been without having felt the singular charm of his personal character? In Sir William, I think, we have a remarkable exemplification of the modesty of true science. Amidst accumulating honours that would have turned many a wise man's head we have found him ever as simple, gentle, unpretending as he is able and accomplished. Therefore we accept the gift you have now offered to us with pleasure and with pride, as the portrait not only of one of the greatest of our teachers, but one of our most valued and accomplished friends."

The Brazilian Government and the Cable Service.—The Rio de Janeiro correspondent of *The Times*, in a letter dated November 9th, states that on the occasion of the latest revolution but one in that country, the Government prevented the sending of telegraphic messages unless the meaning was perfectly clear, and in several instances, even after they had been passed and handed in for transmission, the official took them away, thus causing considerable inconvenience to commercial houses, who in some instances were not aware till the following day that their cablegrams had not been despatched. Fortunately, the British and American Ministers strongly protested, and induced the Government to

Digitized by Google

withdraw their "fiscal" from the cable office. On Sunday evening the Government again sent an official to the cable office to examine messages to and from the south, and this they are still doing. Nothing is definitely known as to their reasons for this, but it is surmised that at the present time fighting is taking place in Rio Grande. It is certain that the Government wires overland have been cut.

The Crystal Palace District Electric Supply Company.—We learn that most satisfactory progress is being made with this Company's installation, and that already the large building, the foundation stone of which was only laid on October 17th last, is roofed in and partly occupied with four 150 H.P. engines. The mains, so far as street work is concerned, are practically completed. Archer pipes have been selected. As our readers are aware, Messrs. J. E. H. Gordon and Co. are the contractors for the work, and the building work is being done by Mr. Fell, of Leamington. It will also be remembered that the Crystal Palace Company had to abandon that part of their district which was situate in Croydon; but we understand that, by a resolution recently approved by the Lighting Committee of the Croydon Corporation, a proposal from the Company to light Westow Hill and its immediate neighbourhood, has been agreed to, the Corporation reserving to itself the rights secured by its own Provisional Order. It will be seen from an account of the meeting of the Electric Installation and Maintenance Company appearing elsewhere in this issue, that that Company has changed its title, and becomes "The Crystal Palace District Electric Supply Company." These results are effected by the resolutions passed at the extraordinary general meeting held yesterday, and which will doubtless be confirmed at the special meeting called for the 19th instant.

Surveying for a Submarine Cable in the Pacific.—The United States steamer "Albatross," says the *Western Electrician*, has ended the first half of the survey of the bed of the ocean for a submarine cable between San Francisco and Honolulu, which was authorised by a special appropriation of $25,000 made by the last Congress. It is considered quite impossible to run a cable from San Francisco direct, for the reason that a plateau extends out for a distance of about 60 miles, with an average depth of only 100 fathoms; but at that point the depth suddenly increases to 1,200 fathoms, proving the existence of a precipice. The whole coast of California does not offer more than a half-dozen places suitable for a cable landing. But comparatively few stretches of sandy beach, free from outlying rocks, exist along the coast, and by far the greater portion of the shore waters are shallow, and the bottom is besprinkled with sharp rocky projections. In the Bill making the appropriation, Congress designated San Francisco as the point from which the cable should be laid, but a poorer location is not to be found on the Pacific coast. It happens, however, that the most eligible site existing is the one nearest San Francisco. This place, which is generally known as Moss Landing, though the Government charts designate it as Salinas Landing, is almost in the centre of the long, clear, sandy beach circling Monterey Bay, and at a point about one mile south of the mouth of the Salinas river. The bay has practically no shipping traffic, hence no injury is to be feared from dragging anchors.

Oxford.—The site selected for the Oxford central station is at Cannon Wharf, by the side of the river, and is in close proximity to the railway. The local authorities, says the *Engineer*, insisted upon a continuous-current system being adopted, and the distance from the station to the centre of the compulsory area, which is about 1,300 yards, necessitated the adoption of a high-pressure primary system, with transformers. The plant now to be installed consists of three locomotive multitubular boilers, working at 160lb. pressure, supplying steam to three vertical triple-expansion surface-condensing 135 H.P. engines. Each engine will drive a separately excited Elwell-Parker dynamo, having an output of 1,050 volts and 80 amperes. From the generating station two pairs of high-pressure cables will run to a switch station situated near the centre of the district to be lighted. The whole of the distribution and regulation of the supply will be carried out from this place. At the switch station these cables will connect on to a pair of omnibus bars, from which current will be supplied to continuous-current transformers, situated at the switch station and at various sub-stations throughout the district. The starting and stopping of the transformers is to be carried out entirely from the switch stations without any attention at the sub-stations. The transformers are each to have an output of 107 volts and 360 amperes, running at a speed of 550 revolutions, with an efficiency of 90 per cent. at full and 80 per cent. at one-third load. The station will, it is anticipated, be running for the supply of current early in the new year.—We understand that the Electric Installation and Maintenance Company has applied for powers to transfer its Oxford Order to the Oxford Electric Light Company.

The Chicago Exhibition.—Our Chicago contemporary, *Electricity*, in its issue of November 18th, contains the following remarks, under the heading of "A Strange Proceeding":—"The English Royal Commission, which has charge of all exhibits to the Fair from Great Britain and her colonies, has just raised a very important question. It has issued a circular informing all English exhibitors that they must pay for space in the World's Fair buildings at rates ranging from 60 cents to $1.20 per square foot. In their official notice, members of the Commission say that they are compelled to charge for space on account of the meagre appropriation of Her Majesty's Government. For months Director-General Davis has been sending printed matter to Europe, informing prospective exhibitors that no charge would be made for space in the buildings. When the English Commissioners were in Chicago he gave them 250,000 square feet free of charge, and promised to give them more if needed. Colonel Davis does not understand that the English Commission has any authority to collect money from exhibitors. He is now in correspondence with Sir Henry Trueman Wood, secretary, to learn why the charge is levied. Officials of the Fair believe the action of the English Board will injure the Exposition abroad, especially if the precedent should be followed by other countries. At the Paris Exposition no charge was made for floor space, but the managers made an assessment for 'flooring,' which caused much complaint."—A notice published in the *London Gazette* announces that the protective sections of the Trade Marks Act of 1883, in regard to inventions sent to an industrial or international exhibition, shall apply to the Chicago Exhibition of 1893, the exhibitors, however, being relieved from the conditions specified as to the giving notice of their intention to exhibit.

The Comparative Cost of Electric and Horse Traction on the Continent.—In a Paper recently read before the Vienna Society of Engineers, Herr H. Koestler gave some interesting figures with regard to the cost of electricity and horses for tramway work. We are indebted for our information to an abstract in *La Lumière Electrique*, of November 14th. The figures being mostly comparative have been left as in the original in car kilometres, and centimes per car kilometre; but to transform them into car miles and pence per car mile we have only to multiply them respectively by ·62 and ·16. Herr Koestler first of all compared the Moedling-Hinterbrühl electric line (4·5 km.) with the Liesing-Kalterleutgeben ordinary line (6·7km.), which are worked under almost identical conditions; the outgoings per car kilometre are respectively 31 and 25 centimes, and the net earnings 52 and 10·7 centimes. The next lines compared are the Frankfort-Offenbach electric line and the Frankfort horse-car system The gross receipts per car kilometre are respectively 33·75 and 67·15 centimes, total working expenses 30 and 59 centimes; net earnings, 3·75 and 8·15 centimes. It will be seen that the working expenses of electricity are 50 per cent. less than those of horses, but the large traffic on the horse lines turns the net balance in their favour. In January, 1890, the Budapest electric lines were 6 and the horse lines were 45·6 kilometres long, and the car kilometres run were respectively 291,262, and 5,440,400. The receipts per car kilometre were respectively 71·16 and 58 centimes, and the expenses respectively 35·5 and 43 centimes; so that what Herr Koestler terms the "exploitation coefficient" comes out at 74 per cent. for horses, and 50 per cent. for electricity; and even this is unduly favourable to the horse-cars. The Budapest horse-cars are, moreover, worked exceptionally cheaply; in Vienna, for instance, the exploitation coefficient is 92 per cent.

ELECTROMAGNETIC THEORY.—XX.

BY OLIVER HEAVISIDE.

(*Continued from page 28.*)

§ 103. We should, in the first place, fix how to represent vectors, although in reality this is the outcome of experience. A vector may obviously be denoted by a single letter; and, having defined certain letters to stand for scalars and others for vectors, it is certainly unnecessary that the vectors should be distinguished from the scalars by the use of different kinds of types. But practical experience shows that it is very desirable that this should be done, in order to facilitate the reading of vectorial work, by showing at a glance which letters are vectors and which are scalars, and thus easing the stress and strain on the memory. This is all the more important because the manipulation of vectors sometimes differs from that of scalars.

Now Prof. Tait usually indicates vectors by Greek letters. But it is well known that a considerable familiarity with the Greek letters—such as is acquired by studying the literature of ancient Greece—is required before they can be read and manipulated with facility. On the other hand, few are Greek scholars, and in fact many people think it is about time the dead languages were buried. Greek letters are, at any rate, not very well adapted to a vector analysis which aims at practicality.

Maxwell employed German or Gothic type. This was an unfortunate choice, being by itself sufficient to prejudice readers against vectorial analysis. Perhaps some few readers who were educated at a commercial academy where the writing of German letters was taught might be able to manage the German vectors without much difficulty; but to others it is a work of great pains to form German letters legibly. Nor is the reading of the printed letters an easy matter. Some of them are so much alike that a close scrutiny with a glass is needed to distinguish them, unless one is lynx-eyed. This is a fatal objection. But, irrespective of this, the flourishing ornamental character of the letters is against legibility. In fact, the German type is so thoroughly unpractical that the Germans themselves are giving it up in favour of the plain Roman characters, which he who runs may read. It is a relic of mediæval monkery, and is quite unsuited to the present day. Besides, there can be little doubt that the prevalent shortsightedness of the German nation has (in a great measure) arisen from the character of the printed and written letters employed for so many generations, by inheritance and accumulation. It became racial; cultivated in youth, it was intensified in the adult, and again transmitted to posterity. German letters must go.

Rejecting Germans and Greeks, I formerly used ordinary Roman letters to mean the same as Maxwell's corresponding Germans. They are plain enough, of course; but, as before mentioned, are open to objection. Finally, I found salvation in **Clarendons**, and introduced the use of the kind of type so called, I believe, for vectors (*Phil. Mag.*, August, 1886), and have found it thoroughly suitable. It is always in stock; it is very neat; it is perfectly legible (sometimes alarmingly so), and is suitable for use in formulæ along with other types, Roman or italic, as the case may be, contrasting and also harmonising well with them.

Sometimes block letters have been used; but it is sufficient merely to look at a mixed formula containing them to see that they are not quite suitable. I should mention here, however, that it is not the mere use of special types that converts scalar to vector algebra. For instance, engineers have often to deal with vector magnitudes in their calculations, but not (save exceptionally) in their vectorial signification. That is, it is merely their size that is in question, and when this is the case there is no particular reason why a special kind of type should be used, whether blocks or another sort.

In connection with Clarendon type, a remark may be made on a subject which is important to the community in general. I refer to the retrograde movement in typography which has been going on for the last 20 years or so. Many people, who possess fairly good and normal eyesight, find a difficulty in reading printed books without straining the eyes, and do not know the reason. They may think the print is too small, or that the light is not good, or that their eyes are not right. But the size of type *per se* has little to do with its legibility; a far more important factor is the style of type, especially as regards the fineness of the marks printed. The "old style," revived a generation since, and now largely in use, differs from the more legible "modern style" (of this page, for instance) in two respects. It has certain eccentricities of shape, which make it somewhat less easy to read; but, more importantly, the letters on the types are cut a good deal finer, which results in a pale impression, as if the ink were watery. This is the main cause of the strain upon the eyes, and the good light wanted. Even very small print is easy to read if it be bold and black, not thin and pale. It would be a public benefit if the retrograde step were reversed, and the revived old style, which threatens to drive out the modern style, discarded. Not that the latter is perfect. A still better style would be arrived at by thickening the fine lines in it, producing something intermediate between it and the Clarendon style (which last, of course, would be too much of a good thing). As everyone who has had to read MSS. knows, the most legible handwritings—irrespective of the proper formation of the letters—are those in which the writing-master's fine upstroke is discarded. Now it is the same in print. Thicken the fine lines, and the effect is magical.

§ 104. The tensor of a vector is its size, or magnitude apart from direction. Other important connected quantities are its three rectangular scalar components—the Cartesian components—which are the tensors of the three rectangular vector components. It is usual, in Cartesian work, to use three separate letters for these components, as F, G, H; or u, v, w; or ξ, η, ζ, &c. One objection to this practice is that when there s a large number of vectors the memory is strongly taxed to remember their proper constituents. Another is the prodigal waste of useful letters. One alphabet is soon exhausted, and others have to be drawn upon.

In my notation the same letter serves for the vector itself, and for its tensor and components. Thus, $\mathbf{E}$ denoting any vector, its tensor is E, and its components are E_1, E_2, E_3. Similarly, the tensor of $\mathbf{a}$ is a, and the components are a_1, a_2, a_3. A large stock of letters is thus set free for other use.

But a remark must be made concerning MS. work, as distinguished from printed work. In MS. work it is inconvenient to be at the trouble of writing two kinds of letters; ordinary letters will suffice for both scalars and vectors. Or the ordinary letters representing vectors may receive some conventional mark to vectorise them. But, presuming ordinary letters are written, something is required to distinguish between the vector and its tensor. This may be satisfied by calling E_0 the tensor of $\mathbf{E}$. Only when an investigation is to be written out for the printers is it necessary to bring in special letters, and this is most simply done by a conventional mark affixed to every (to be) vector. Compositors are very intelligent, read mathematics like winking, and carry out all instructions made by the author.

If a vector $\mathbf{a}$ be multiplied by a scalar x, the result, written $x\mathbf{a}$ or $\mathbf{a}x$, is a vector x times as big as $\mathbf{a}$, and having the same direction. Thus, if $\mathbf{a}_1$ be a unit vector parallel to $\mathbf{a}$ (or, more strictly, parallel to and concurrent with $\mathbf{a}$), of unit length, we have $\mathbf{a} = a\mathbf{a}_1$. It is sometimes useful to separately represent the direction and length of a vector, and the above is a convenient way of doing it without introducing new letters. This applies to any vector. But it need not be an absolute rule. For instance, the Cartesian co-ordinates x, y, z of a point may be retained. Thus, let $\mathbf{r}$ be the vector from the origin to any point, and let $\mathbf{i}$, $\mathbf{j}$, $\mathbf{k}$ be unit vectors from the origin along the three rectangular axes. We shall then have

$$\mathbf{x} = x\mathbf{i}, \quad \mathbf{y} = y\mathbf{j}, \quad \mathbf{z} = z\mathbf{k}, \quad . \quad . \quad (1)$$

where $\mathbf{x}$ is the vector projection of $\mathbf{r}$ on the $\mathbf{i}$ axis, as we know by the elementary geometry of a rectangular parallelepiped or brick. Also, the direction-cosines of $\mathbf{r}$ are x/r, y/r, r/z, and

$$r^2 = x^2 + y^2 + z^2, \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

by Euclid I., 47.

§ 105. This brings us to vector addition. The vector $\mathbf{x}$ signifies translation through the distance x in the direction $\mathbf{i}$.

Digitized by Google

If, now, after performing this operation, we carry out the operation indicated by **y**, viz., translation through the distance y in the direction **j**; and, lastly, carry out the operation **z**, or translation through the distance z in the **k** direction, we shall arrive at the end of the vector **r**. That is, starting from one corner of a brick, we may reach the opposite corner by three mutually perpendicular journeys along three edges of the brick. The final result is the same as if we went straight across from corner to corner, that is, by carrying out the operation indicated by the vector **r**. This equivalence is expressed by

$$\mathbf{r} = \mathbf{x} + \mathbf{y} + \mathbf{z}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

Or, by (1),

$$\mathbf{r} = x\mathbf{i} + y\mathbf{j} + z\mathbf{k}. \quad . \quad . \quad . \quad . \quad . \quad (4)$$

The meaning of addition of vectors in this example is simply the carrying out of the operations implied by the individual vectors added, the geometrical vector meaning a displacement in space, or translation from one point to another. The order of addition is indifferent, since there are six ways of going from one corner to the opposite one of a brick along its edges.

We see that any vector may be expressed as the sum of three mutually perpendicular vectors, viz., its vector projections on its axes. Furthermore, by the use of a skew parallelepiped instead of a brick we see that any vector may be expressed as the sum of three other vectors having any directions we please, provided they are independent, or not all in the same plane. For in the latter case the parallelepiped degenerates to a plane figure.

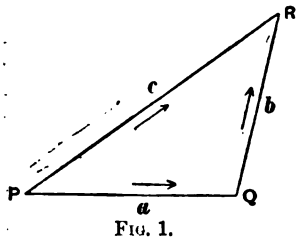

Fig. 1.

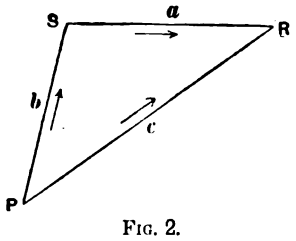

Fig. 2.

But it is perhaps best to explain vector addition in general without any reference to axes. Thus let **a** and **b** be vectors to be added, **a** meaning translation from P to Q in the first figure, or through an equal distance along any parallel line, as from S to R in the second figure, whilst **b** means translation from Q to R in the first figure, or through an equal distance along any parallel line, as from P to S in the second figure. In the first case, performing the operation **a** first, and then **b**, we go from P to R *viâ* Q; in the second case, with **b** first and then **a**, we go from P to R *viâ* S. The final result in either case is equivalent to direct translation from P to R, symbolised by the vector **c**. Thus,

$$\mathbf{c} = \mathbf{a} + \mathbf{b} = \mathbf{b} + \mathbf{a}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

The above may be extended to any number of vectors. Or we may reason thus:—Let **A** be any given vector, translating, say, from P to Q. We need not go from P to Q direct, but may follow any one of an infinite number of paths, as for example,

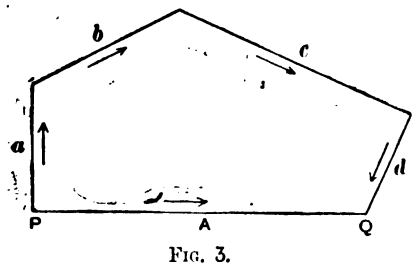

Fig. 3.

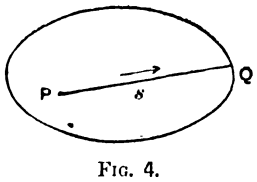

Fig. 4.

$\mathbf{a}+\mathbf{b}+\mathbf{c}+\mathbf{d}$ in the figure. The final result of the successive translations is always the same, viz., the direct translation **A**.

Or

$$\mathbf{A} = \mathbf{a} + \mathbf{b} + \mathbf{c} + \mathbf{d}. \quad . \quad . \quad . \quad . \quad . \quad (6)$$

Thus any vector **A** may be split up into the sum of any number n of vectors, of which $n-1$ are perfectly arbitrary, for instance **a**, **b**, **c** in the figure. The remaining one **d** is, of course, not arbitrary. It is the vector required to complete the circuit of vectors.

The vectors need not be in one plane. Nor need the path followed consist of finite straight portions. It may be wholly or partly curved. The curved portions are then made up of infinitesimal vectors. Each curved portion may be replaced by the vector joining its terminals.

Since the original vector and the substituted vectors form a circuit, if the positive direction in the circuit be the same for all the vectors, we may express vector addition thus:—The sum of any number of vectors which make a circuit is zero. That is, $\Sigma\mathbf{a} = 0$, if **a** is the type of the vectors summed. For a curved circuit we shall have

$$\int d\mathbf{s} = 0, \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

where $d\mathbf{s}$ is the vector element of the circuit. Here **s** itself may be taken to be the vector from *any* fixed point P to a point Q on the circuit. Then $d\mathbf{s}$ is the infinitesimal change in **s** made in an infinitesimal step along the circuit, that is, it is the vector element of the circuit itself.

In a vector equation every term is a vector, of course, however the individual terms may be made up, and every vector equation expresses the fact symbolised by (7), or by $\Sigma\mathbf{a} = 0$ when the vectors are finite. In the latter case, **a** may be also regarded as $\Delta\mathbf{s}$, the *finite* change in the vector **s** from any fixed origin produced by passing from beginning to end of the vector **a**.

The $-$ sign prefixed to a vector is the same as multiplication by -1, and its effect is simply to reverse the direction of translation. Or it may be regarded as reversing the tensor, without altering the direction: thus

$$-\mathbf{a} = -a\mathbf{a}_1 = a \times (-\mathbf{a}_1) = (-a) \times \mathbf{a}_1 \quad . \quad . \quad (8).$$

Thus, in any vector equation, for example

$$\mathbf{a} + \mathbf{b} + \mathbf{c} + \mathbf{d} + \mathbf{e} + \mathbf{f} = 0, \quad . \quad . \quad . \quad . \quad (9)$$

we may transfer any terms to the other side by prefixing the $-$ sign. Thus,

$$\mathbf{a} + \mathbf{b} + \mathbf{c} - = -\mathbf{d} - \mathbf{e} - \mathbf{f} = -(\mathbf{d} + \mathbf{e} + \mathbf{f}) \ldots \quad . \quad (10)$$

In the form (9) we express the fact that translation in a circuit is equivalent to no translation. In (10), however, we express the equivalence of two translations by different paths from one point to another.

If any trouble be experienced in seeing the necessary truth of (9) for a circuit in whatever order the addition be made, the matter may be clinched by means of **i**, **j**, **k**, the unit rectangular vectors; as we saw before, the resolution of vectors into rectangular component vectors depends only upon the properties of the right angled triangle. Thus split up the vectors **a**, **b**, **c** into components, we have

$$\left.\begin{aligned} \mathbf{a} &= \mathbf{i}\,a_1 + \mathbf{j}\,a_2 + \mathbf{k}\,a_3, \\ \mathbf{b} &= \mathbf{i}\,b_1 + \mathbf{j}\,b_2 + \mathbf{k}\,b_3, \\ \mathbf{c} &= \mathbf{i}\,c_1 + \mathbf{j}\,c_2 + \mathbf{k}\,c_3, \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (11)$$

Now add up. All vectors parallel to **i** add in scalar fashion, for there is no change of direction. Similarly for **j** and **k**; so we have

$$(\mathbf{a} + \mathbf{b} + \mathbf{c}) = \mathbf{i}\,(a_1 + b_1 + c_1) + \mathbf{j}\,(a_2 + b_2 + c_2) + \mathbf{k}\,(a_3 + b_3 + c_3).$$

Now the scalar additions may be done in any order we please. It follows that the same is true in vector addition. The addition and subtraction of vectors and transfer from one side of an equation to the other are thus done identically as in the algebra of scalars. Addition has, it is true, not the same meaning, but the vector meaning is not inconsistent with the scalar meaning, and, in fact, includes the latter as a particular case. There is never any conflict between $+$ put between vectors and $+$ put between scalars.

§ **106.** In the above we have referred entirely to the geometrical vector. But a very important step further can be made referring to physical vectors, a step which immediately does away with piles of ingeniously constructed and brain-wasting "demonstrations," especially compiled for the torturing of students and discouragement of learning. If a quantity be recognised to be a directed magnitude, it is, in its mathematical aspect, a vector, and is therefore subject to the same laws as *the* vector, or geometrical vector. So, just as we have the triangle, or parallelogram, or polygon of geometrical vectors, we must have the same property exemplified in the addition of all vectors, as velocity, acceleration, force, &c. This identity of

Digitized by Google

treatment applies not only to the addition property, but to the multiplication and other properties to be later considered. We may symbolise a physical vector by a straight line of given length and direction.

It used to be thought necessary to give demonstrations of the parallelogram of forces, perhaps even before the student knew what force meant. I have some dim recollection of days spent in trying to make out Duchayla's proof, which was certainly elaborate and painstaking, though benumbing. Maxwell, in his treatise, elaborated a demonstration that electric currents compounded according to the vector law. But surely there is something of the vicious circle in such demonstrations. Is it not sufficient to recognise that a quantity is a vector, to know that it follows the laws of the geometrical vector, the addition property of which does not want demonstrating, but only pointing out, as in the polygon of vectors?

Although this is not the place for exercises and examples, yet it is worth while to point out that by means of the addition property of vectors a good deal of geometry can be simply done—better than by Euclid, a considerable part of whose 12 books consists of examples of how not to do it (especially Book V.). There is a Society for the Improvement of Geometrical Teaching. I have no knowledge of its work; but as to the need of improvement there can be no question whilst the reign of Euclid continues. My own idea of a useful course is to begin with arithmetic, and then, not Euclid, but algebra. Next, not Euclid, but practical geometry, solid as well as plane; not demonstrations, but to make acquaintance. Then, not Euclid, but elementary vectors, conjoined with algebra, and applied to geometry. Addition first; then the scalar product. This covers a large ground. When more advanced, bring in the vector product. Elementary calculus should go on simultaneously, and come into the vector algebraic geometry after a bit. Euclid might be an extra course for learned men, like Homer. But Euclid for children is barbarous.

(To be continued.)

THE DISSIPATION OF ENERGY THROUGH REVERSALS OF MAGNETISM IN THE CORE OF A TRANSFORMER.

At a meeting of the Cavendish Physical Society, Cambridge, on Tuesday, Prof. Ewing communicated the preliminary results of experiments on this subject, which had been made by him in conjunction with Miss H. G. Klaassen. The particular object of the inquiry was to test whether the reputed reduction of loss through hysteresis when a transformer is loaded actually takes place. A reduction of loss when the transformer was loaded had appeared to take place in trials by Prof. Ryan, Mr. Mordey, and Prof. Ayrton; but the results were, perhaps, scarcely decisive, for in most of these experiments the loss was determined not directly, but as the difference between two relatively great quantities. The method of measurement now used was a direct one, described by Prof. Ewing in *The Electrician* of October 9th. Two precisely similar transformers were wound, the core consisting in each case of a ring of insulated iron wire, over which there were two equal primaries and two equal secondaries. But the primaries of one transformer were wound so as to oppose each other, and the secondaries of the same transformer were also wound so as to oppose each other. The result was that that transformer was magnetically inactive whatever current was passed through its primary or its secondary. The two transformers were connected in series; the same alternating magnetising current traversed the primaries of both, but produced no magnetic effect on the inactive one. And when the secondary circuit was closed, the inactive secondary was included in series with the active secondary. Hence the Joule effects, that is to say the amounts of heat developed on account of the resistance of the primary and secondary coils, were identical in both. The active transformer tended to become hot faster than the other, because of hysteresis and Foucault currents in the core; but the rate of heating of the inactive core was made as great as that of the active one by passing a current of regulated strength through its iron wire. Equality of temperature was maintained in this way, the equality being tested by thermo-electric junctions imbedded in each core. From first to last it was a *nul* method, and experiments showed it to be capable of giving consistent and satisfactory results. If the balancing current was wrong by five per cent., a few seconds of steady working sufficed to produce a difference of temperature sufficient to indicate whether the current should be adjusted to a stronger or weaker value. The strength of this current served, of course, to measure the power which was being wasted in the core of the active transformer. To secure that the magnetic induction **B** should have the same value throughout a series of tests under various loads, the device was adopted of winding on the transformer a short "tertiary," or special induction coil, which was connected to a hot-wire voltmeter of very simple construction. A liquid rheostat in the primary circuit allowed the primary current to be regulated so that the limits of magnetisation remained unchanged when the secondary current was varied. The alternating primary currents were derived from a larger transformer, which, in its turn, was excited by a commutated current from a storage battery. The frequency of the reversals was maintained constant by the aid of a tuning fork, with which the hum of the exciting transformer was kept in unison. The purpose in using an exciting transformer was to secure more nearly sinusoidal currents than would have been given had the commutator been directly connected with the transformer under test.

After adjusting the balancing current in the iron wire of the inactive transformer while the secondary circuit was open, so that the rate of heating by that current in the inactive core was just equal to the rate of heating through hysteresis and Foucault currents in the active core, the secondary circuit was closed through a resistance small enough to load the transformer heavily, and the primary current was increased to bring **B**, as tested by the "tertiary" volts, to the same value as before.

No difference could be detected in the amount of balancing current required to maintain the equilibrium of temperature. In other words, the loss through hysteresis and Foucault currents in the iron core went on at just the same rate whether the secondary was closed or not, even when the load on the secondary was allowed to be considerably greater than would correspond with the conditions of practice in commercial transformers.

The experiment was varied by transposing the active and inactive coils; by adjusting first when the load was on, and then taking the load off; by using various amounts of resistance in the secondary circuit; by using various frequencies, ranging from about 100 to 130 cycles per second; by working with several different degrees of maximum induction, **B**, ranging from about 6,000 to 12,000 C.-G.-S. In no case did a difference in the core loss show itself when the load was put on or taken off.

The experiments seem decisive of the point at issue, at least to this extent, that if an alteration of as much as 5 per cent. in the strength of the balancing current had been necessary it would have been detected. In point of fact, no alteration was found to be necessary.

The experiments are being continued with the object of making absolute measurements of the loss through hysteresis under various frequencies and various intensities of induction, and of comparing the loss in reversals under the conditions of a transformer with the loss that is represented by $\int \mathbf{H}\, d\mathbf{I}$ in slowly performed magnetic cycles.

Telegraphic Communication with the Transvaal.—At last measures are being taken, says *South Africa*, for the purpose of bringing the Transvaal in direct communication with Delagoa Bay by wire. There is a distance of under a hundred miles to be spanned by the wire, when direct communication between Pretoria and Delagoa Bay, through Barberton, will be attained. This is a convenience long looked forward to, and when attained will be a great boon to the State, and to these fields especially. As it is now, we have to send a wire to Delagoa Bay, *vid* Natal, and so have to pay cable tariff.

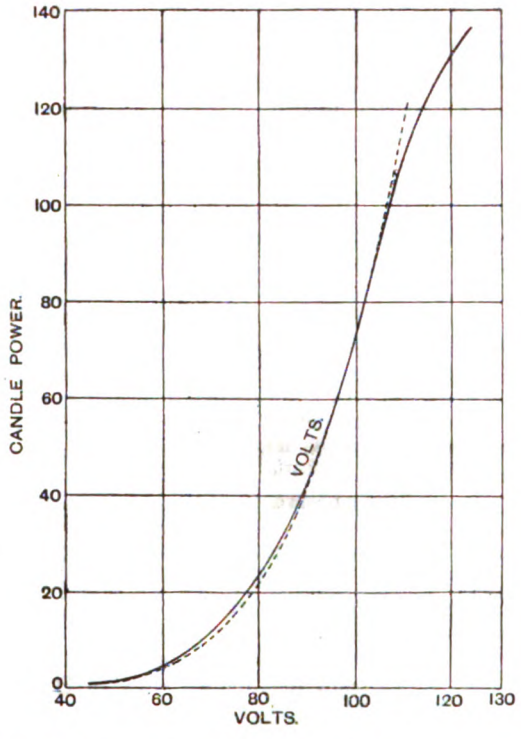
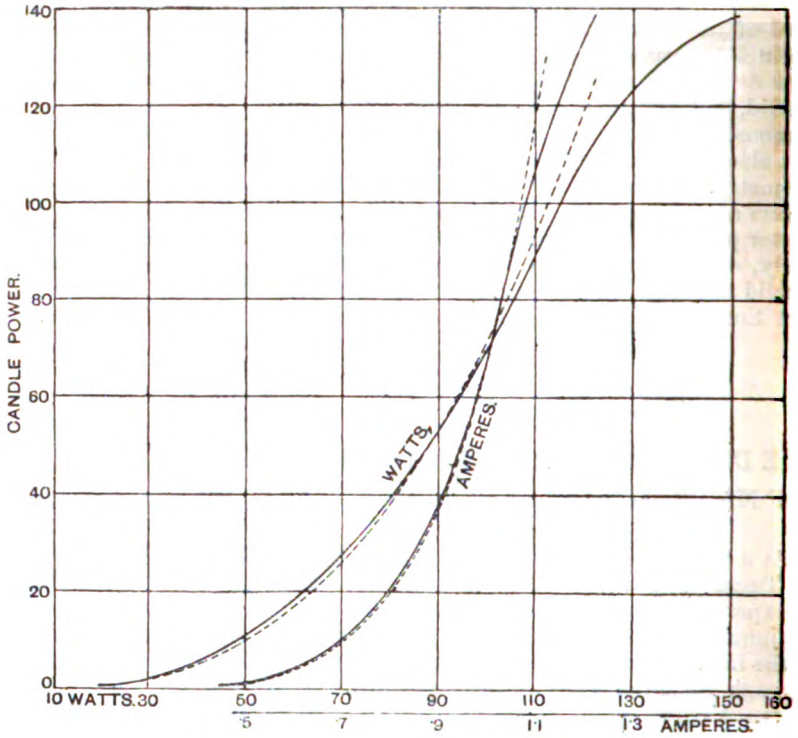
ON THE CANDLE-POWER OF INCANDESCENT LAMPS AS RELATED TO CURRENT, VOLTAGE, AND ENERGY CONSUMED.*

BY LOUIS A. FERGUSON AND DAVID A. CENTER.

The observations described in the present Paper have for their object the study of the relation between the illuminating power of various incandescent lamps now in use, and the current, potential, and expenditure of energy used in operating them. The observations were made in the spring of 1888, but various circumstances have delayed their publication till the present time.

The subject has already been considered by several persons, and it has appeared that for such lamps as have been tested the candle-power is approximately proportional to the cube of the current, and to the fifth power of the potential difference between the terminals of the lamps. It seemed to us, however, that it was desirable to carry out a series of tests with more recent lamps, and with a greater variety of them than had been employed in former experiments upon the subject. It was also thought that a consideration of the relation between the candle-power and the potential difference between the terminals of the lamp (or electrical pressure) would be useful.





We considered it best, on the whole, to express our results in the form of a simple exponential equation of the form $y = a x^n$, as has been customary, notwithstanding the fact that, as Götz has shown,† at least for the relation between candle-power and energy expended, the results of experiments are more accurately expressed by an equation of the form $y = a x + b x^n$.

The greater simplicity of the common formula has decided advantages in its practical application which go far to make up for the somewhat diminished accuracy at extreme values of the candle-power, while within quite wide ranges it is amply exact for all practical purposes.

There were tested in all twenty-one lamps, including those made by the Edison, United States, Thomson-Houston, and Westinghouse Companies, having in every case a good normal filament. The photometric measurements were made with a Bunsen photometer. The lamp to be tested was placed in the circuit of an Edison or Westinghouse direct-current dynamo, from either of which machines an electromotive force of 110 volts could be obtained, and by coupling the two machines in series the lamp could be put into a circuit having a potential of 220 volts.

In the same circuit with the lamp to be tested was placed a Thomson graded current galvanometer, by which the current could be measured with ease within 1 per cent. The difference of potential at the terminals of the lamp was measured by a Thomson potential galvanometer, whose readings also could be depended upon to at least 1 per cent. The product obtained by multiplying the current in amperes by the difference of potential at the terminals of the lamp in volts, gave the rate in watts at which energy was consumed in the lamp at any given time.

The necessary variation in the current and electromotive force in the working circuit was accomplished by means of a set of six Edison lamps placed in the circuit, with connections between the lamps so arranged that any number of lamps could be thrown out of circuit at a time, or two or three thrown in parallel with each other, thus giving a wide range of variation of resistance. For smaller variations a set of German silver resistance coils was constructed and arranged so that changes from one-fourth of an ohm up to 75 ohms could readily be secured. A Methven slit was used as a standard of light.

In all cases, except with those of the United States Company, the lamps were placed so that the plane of the filament was at right angles to the plane of the bar. They were kept in this position throughout the test. The United States lamps were placed so that the plane of the filament made an angle of 45 degrees with the bar.

The lamps were first started at about two-tenths of a candle-power, the resistance in circuit then being decreased until a suitable reading was obtained on the photometer, when a series of twelve or more readings was made of the candle-power by one observer, while the other, as often as possible during the interval, read the current in the circuit and the potential at the terminals of the lamp. The resistance was again changed and new measurements taken of the candle-power, current, and potential, this mode of procedure being continued in most cases until the filament gave way. In some cases it was not broken in the first test, and a second run on the lamps was made. In every such instance it was found that the curve of relation ran lower than in the first test, showing that the effect upon the lamp was to decrease its efficiency, more energy per candle being consumed in the second run. It was also found, in a few instances where it was impossible to finish a test of the lamp on the same day that it was begun, that on resuming the test it required more energy per candle than on the first day, until after some fifteen minutes had elapsed, when the original values were again obtained.

As a matter of some interest, several tests were made upon some of the Edison lamps to find out, if possible, about how much energy must be expended in such a lamp in order that the first appearance of light might be distinguished with the naked eye in a positively dark room. It was also thought to be of interest to know the colour of the light in this case. Measurements were made of the current and potential, and it was found that the mean value of the energy expended when the light first became visible to the most sensitive observer was about 0·74 watt. The colour of the light emitted by the filament was in all cases of an ashy grey.

Nearly every style of lamp seemed to have one particular place at which the filament gave way. The Edison filament, in every

Digitized by Google

instance but one, broke at from one-eighth to one-half an inch above the platinum joint on the right-hand side, looking at the labelled side of the globe. The circuit wires were removed from the lamp-socket before this fact was noted, so that we are unable to state whether this was the positive or negative side. The filament of the Weston lamps always broke at about one inch from the top, while that of the Thomson-Houston lamps broke at the top. One of the Westinghouse lamps broke at about one-eighth of an inch above the middle point of the right-hand side of the filament, looking at the labelled side of the globe; another broke at about one-eighth of an inch above the joint on the same side. In nearly all the lamps tested the joints were noticed to be very black, due to deposition of carbon by the Crookes' effect.

A series of curves was constructed, showing graphically the relations between the candle-power and the current, potential, and energy expended, and equations of the form $y=ax^n$ satisfying the observed values of the variables were determined by the method of least squares for the various lamps in the case of the current and energy determinations. In these the candle-power is denoted by y and the other variable by x. From these equations others, giving the relation between the potential and candle-power, were calculated. This calculation, together with other aid in the preparation of some of our tables, we owe to the kindness of Mr. Edward Collins, Jr., of the Rogers Laboratory.

We had observed that in nearly all cases as the lamp approached the breaking-point the curve ceased to run up with its usual steepness, the candle-power falling off very rapidly. In the calculations of the equation for each lamp, all observations above this point at which the curve fell off were neglected as being of no value for our determinations. This we felt justified in doing, since our object was to deduce an equation which would show the relation between the candle-power and current, or other variable, as long as the former increases regularly with the latter. We calculated the equation for each separate lamp, and from these deduced, by the usual method, a general equation applying to each particular kind of lamp. Below are given a few specimens of the individual equations, as well as the general equations calculated from them.

The Edison lamps used were of the "new style," 3·1 watts per candle-power, and the Weston lamps were the "tamadine lamps."

EDISON, 16 c.p., 110 volts.

(A) $y=500\ x^{5\cdot3}$

(B) $y=540\ x^{5\cdot0}$

GENERAL EQUATION $v=520\ x^{5\cdot1}$

EDISON, 10 c.p., 110 volts.

(C) $y=490\ x^{4\cdot7}$

THOMSON-HOUSTON, 16 c.p., 75 volts.

(H) $y=0\cdot000157\ x^{2\cdot8}$

(J) $y=0\cdot000153\ x^{2\cdot8}$

GENERAL EQUATION $y=0\cdot000155\ x^{2\cdot8}$

The following equations showing the relation between the candle-power and potential difference between the lamp terminals, as already stated, were calculated from the preceding equations, except in the case of (F) (G) (P), which were obtained directly from the observed results.

EDISON, 16 c.p., 110 volts.

(A) $y=0\cdot000000000000021\ x^{7\cdot3}$

(B) $y=0\cdot000000000000151\ x^{6\cdot8}$

GENERAL EQUATION $y=0\cdot0000000000000082\ x^{7\cdot4}$

EDISON, 10 c.p., 110 volts.

(C) $y=0\cdot0000000000000082\ x^{6\cdot2}$

THOMSON-HOUSTON, 16 c.p., 75 volts.

(H) $y=71\cdot5\ x^{6\cdot2}$

(J) $y=68\cdot9\ x^{6\cdot6}$

GENERAL EQUATION $y=74\ x^{6\cdot9}$

In like manner were obtained the relations between the candle-power and the energy expended, which are as follows:—

EDISON, 16 c.p., 110 volts.

(A) $y=0\cdot000065\ x^{3\cdot1}$

(B) $y=0\cdot000131\ x^{2\cdot9}$

GENERAL EQUATION $y=0\cdot000098\ x^3$

EDISON, 10 c.p., 110 volts.

(C) $y=0\cdot000087\ x^3$

THOMSON-HOUSTON, 16 c.p., 75 volts.

(H) $y=0\cdot0000000037\ x^{5\cdot1}$

(J) $y=0\cdot0000000003\ x^{5\cdot7}$

GENERAL EQUATION $y=0\cdot0000000011\ x^{5\cdot4}$

Although our general equations would be much enhanced in value if we could have employed a larger number of each kind of lamp in our investigations, there are, nevertheless, certain facts that are clearly evident from our results. The lamps at present used, like the earlier ones, increase in candle-power about as the fifth power of the current employed, and as the cube of the energy expended. It will also be seen that the candle-power increases about as the sixth power of the potential difference between the terminals of the lamp. The average value of the exponent of x, the candle-power for the current equations, is 5·3; for the energy equations, 2·9; and for the potential difference equations, 6·4.

To illustrate the agreement of the exponential equations with the observed relations between candle-power and current, potential difference, and energy expended, the curves shown in Figs. 1, 2, 3, were plotted for the Thomson-Houston 16 c.p., 75-volt lamp. The equations used were the individual ones for that special lamp.

"Le Gaz et ses Applications." Par E. de Mont-Serrat et E. Brisac. Bibliothèque des Connaissances utiles. (Paris: J. B. Baillière et Fils.) Price 4 francs.

"The Mechanical Engineer's Pocket-Book." By D. Kinnear Clark, M.Inst.C.E. (London: Crosby Lockwood and Son.)

"Glasgow and West of Scotland Technical College Calendar for 1891-92."

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

FRIDAY, December 4th. (To-day.)

INSTITUTION OF CIVIL ENGINEERS.

2 p.m. Students' visit to inspect the new Refrigerating Plant at Nelson's Wharf, Lambeth.

PHYSICAL SOCIETY.

5 p.m. Papers to be read:—(1.) "On a Permanent Magnetic Field." By W. Hibbert. (2.) "Note on the Production of Rotatory Currents." By Prof. Ayrton, F.R.S.

OLD STUDENTS' ASSOCIATION.

7:30 p.m. Smoking Concert at Masons' Hall Tavern

MONDAY, December 7th.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

TUESDAY, December 8th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read with a view to discussion:—"The Sale of Water by Meter in Berlin." By Henry Gill, M. Inst. C.E.

WEDNESDAY, December 9th.

SOCIETY OF ARTS.

8 p.m. Ordinary meeting. Paper to be read:—"The World's Columbian Exposition at Chicago in 1893." By James Dredge.

THURSDAY, December 10th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Annual General Meeting. Election of Council and Officers, after which a Paper will be read:—"On the Specification of Insulated Conductors for Electric Lighting and other purposes." By W. H. Preece, F.R.S.

FRIDAY, December 11th.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. Paper to be read:—"Meters for Recording the Consumption of Electrical Energy." By C. H. Wordingham, A.K.C., Stud. Inst. C.E.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices:

SALISBURY COURT, FLEET ST., LONDON, E.C.

Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*" *All Editorial letters to be addressed to the Editor.*

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from Publishing Offices as above.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Old Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	23 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday.*

SMALL ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

SPECIAL NOTICE.—IN ACTIVE PREPARATION.

THE MICROPHONE IN AMERICA.

Although it seems but yesterday that Prof. HUGHES made public his curious discovery of the microphone, the announcement of a new microphonic patent comes upon us as a surprise. Our wonder is not lessened perhaps, but rather increased, when we turn back to the records and find that nearly fourteen years have elapsed since that ingenious device came to light in England, and almost as long since it was born again in New York. In the latter place it was christened an original invention and patented straight away, although its English parent had made a present of it to the world at large. The "new" world, however, having accepted it from other hands, has had to pay for it pretty stiffly, and with results following which are creating astonishment even in the land where patents are commonly worked in defiance of public opinion, and disregard of public rights. We are not sure that the old world, or England in particular, has profited much by Prof. HUGHES' magnanimity; for so soon as the microphone was adapted to the purposes of a telephone transmitter it became patentable here as elsewhere, though the microphone as such could not. But, all the same, we are not likely to grant it a fresh lease of life in that or any other guise; and on this we may congratulate ourselves, as well as commiserate our American brethren, who have just now learnt with dismay that another long patent has

Digitized by Google

been secured for a form of microphone so comprehensive in its claims that telephonic transmission will be almost impossible without its assistance, and its monopoly extended just as if the telephone patent were itself a new invention.

How this has been brought about is rather a long and not very edifying story. Our readers have heard of the Berliner microphone, or telephone transmitter, and by this time have probably forgotten what it was. In reality it was a metallic diaphragm resting on a metal point, both included in a battery circuit; and the inventor distinctly states that the two points must be of metal, and in constant contact, with other conditions equally removed from the microphone principle as known to us more than thirteen years ago. But the claims as set forth, as claims usually do, included a good deal more than the inventor had invented, and one of them runs as follows:—

1. The method of producing in a circuit electrical undulations similar in form to sound waves, by causing the sound waves to vary the pressure between electrodes in constant contact, so as to strengthen and weaken the contact and thereby increase and diminish the resistance of the circuit substantially as described.

These "electrodes" would appear to cover the carbons commonly in use; and the American Courts have ruled, probably on that account chiefly, that the Berliner patent dominates the Edison and other patents; and have allowed it to be issued because it was applied for earlier than any of the rest. But why, the ingenious reader will exclaim, why was it not issued before now if applied for so long ago? We shall have to go as far as New York to find a p'liceman able to answer that question. And, indeed, that kind of functionary would seem to be the right person to apply to; for if what the American technical journals and our New York correspondent tell us is correct, the course of conduct which has enabled this embryo patent to be uncorked and deposited on the Patent Office table as a real live invention, has been of a sort that calls for the stern interposition of the law. Of the leading features of the case there can be no doubt at all. The Edison patent—a subsequent one to that of the Berliner—being secured, and being, we may add, more workable, it was proceeded with. Then there came a godsend in the Drawbaugh litigation—a mere bogus suit, as everybody now believes, which kept the other patents in legal abeyance for eleven long years, although one of them was being exploited most profitably all the while. Both the Berliner and the Edison patents had fallen into one set of hands, with the result, if not the intention, that if the Edison was beaten at law by a superior rival, the Berliner device would be played as a trump card.

This at least is certain. But, as events have recently shown, the retention of the Berliner patent in a condition of suspended animation served the further purpose of putting new life into the Edison instrument, though the Edison patent might be extinguished. We do not understand the law and process of "interference" in the United States Patent Office; but it would seem that by judiciously manipulating the "interferences" provided by the Drawbaugh and Edison and the Berliner and Edison suits, the validity of the latter has been kept undecided until now. That being so, for all practical—or rather for all judicial—purposes, there has been no Edison patent any more than there has been a Drawbaugh patent; and the Berliner patent—poor injured innocent!—is now allowed to claim its rights, of which it has been deprived ever since June, 1877. The Berliner patent dates from now, therefore; and unless anyone powerful enough to interpose successfully steps in, the microphone transmitter will run another 17 years of undisputed, and, we may venture to add, undeserved monopoly. It is as if one had appropriated a wrong umbrella, and after wearing it out taken it back again, getting a new one in its place. You cannot do that in polite society; but you can in the New York Patent Office.

Our information from the locality indicates a strong feeling of indignation at the whole proceeding, and there is talk of invoking the aid of the Legislature to put an end to collusive and injurious "interferences." We sincerely wish success to any endeavours of that kind. But we are not very sanguine as to any useful action being possible as regards the particular case in point. The whole business appears unimpeachable in point of law; and the actors are possessed of great riches to defend what the law has awarded. The investing public in the States are of that opinion, too, for the price of American "Bell" shares—the Bell Company being the owners of both patents—is reported to have risen from 185 to 210 within the last fortnight in consequence of the new patent. It is really a sad, not to say scandalous, business; and we can say this with all the more sincerity because we are not profoundly grieved on our own account. We at least may enjoy free trade in microphone transmitters, none the less for its being protected in America. Perhaps before long we may be manufacturing microphones for exportation to that much be-tariffed country, for the use of the Bell Company itself; and if McKinley will not let us, so much the worse for McKinley and all his works.

THE CHICAGO EXHIBITION EXECUTIVE AND THE ROYAL COMMISSION.

As will be seen by an extract in our "Notes" columns, the action of the Society of Arts in proposing to levy a tax for floor-space upon English firms who are bold enough to exhibit at Chicago in 1893 has, not unnaturally, caused considerable chagrin in that progressive city. The English Commissioners, say the Exhibition officials, were given 250,000 square feet for nothing, and promised more; and here they are endangering the success of the Show by taxing English exhibitors. The disease, however, admits of a simple remedy. We do not suppose that our diplomatic relations with the United States would be very seriously strained if the Chicago Exhibition Executive were to throw over the Royal Commission altogether, and negotiate directly with prospective exhibitors. Since our American friends are so strangely anxious to give their "Fair" a flavour of internationality, why not pay for the fad? In the electrical branch, for example, we feel sure that the designers of the Manchester-square and Kensington Court stations would be ready on receipt of an adequate subsidy to reproduce these typical English central stations on the shores of Lake Michigan; and no doubt one of Mr. Ferranti's 10,000 H.P. abnormities could be loaned from the London Electric Supply Corporation for a trifling consideration. It is a mere question of dollars.

Seriously speaking, however, it seems to us that if, as some assert, it is desirable as a matter of broad policy that Great Britain should be well represented at Chicago, it follows that the Government—the conditions being manifestly so adverse—should not merely be content to refrain from throwing obstacles in the path of English exhibitors, but should actively encourage them. The hostile tariff and the distance are a sufficient discouragement, without the superaddition of a tax of from 2s. 6d. to 5s. per square foot of floor space. It is the meagre Government grant of £25,000 which necessitates this charge; and if it be good policy for us to exhibit at all, it is worth while to substantially increase the sum in order to avoid this obnoxious tax.

By all means let Great Britain be well "represented" at Chicago. We understand that it is proposed to build "an

Digitized by Google

attractive English manor-house" on the Lake front; the Eddystone Lighthouse from the late Naval Exhibition is to be re-erected; and it is said that the model of the "Victory" and a canvas reproduction of the Tower of London are to accompany it. To these might be added a mile or so of good wooden pavement and a few first-rate hansoms. With all this and more of the kind we cordially sympathise, if the expense be not borne by the exhibitor. In the early days of Exhibitions the exhibitor doubtless had his *quid pro quo* for any money expended; and such may still occasionally be the case. But, generally speaking, as things are now it is the promoter rather than the exhibitor who should bear the brunt of the expense, since it is the former and not the latter who reaps the golden harvest; and the relative position of the two parties is in no way altered if the promoter happens to be a great nation or a big city, and the exhibitor an unfortunate foreigner relentlessly harassed by cent. per cent. *ad valorem* duties. Moreover, a little consideration shows us that the exhibitor is a necessary antecedent to the Exhibition. Trade can get along very well now without annual, biennial, triennial, or even decennial Exhibitions; but where would these Exhibitions be without the support of the trade? The question of commercial Exhibitions of manufactures is in short an altogether different one, and we do not propose to reopen it again just at present; but will content ourselves with observing that if money must be spent it would be more profitably devoted to sending round a smart bagman to interview the buyers, according to the favourite American custom, than in displaying machinery to be stared at by mere sightseers, or to be inquisitively scrutinised by rival makers.

REVIEWS.

Testing of Insulated Wires and Cables. By HERBERT LAWS WEBB. (New York: D. Van Nostrand Company.)

This volume contains a series of articles which originally appeared in *The Electrical Engineer*, U.S., and deals solely with the well-recognised methods of determining the insulation resistance, conductor resistance, and electrostatic capacity of submarine telegraph and telephone cables. No doubt it is always difficult for an author to estimate what is the stage of knowledge that his readers have reached. Here the author evidently assumes that those he addresses are familiar with Ohm's and other elementary laws relating to electricity. The book is one of small pretensions, but to those who are making their first attempts to carry out these tests many practical hints are given as to the method of making them and as to the management of the instruments they will have to deal with.

It is impossible in a work of this size to mention all the various methods in practice for arriving at the insulation, conductivity, and capacity of cables; so the author confines his remarks to the direct deflection test for obtaining the insulation resistance, the Wheatstone Bridge for taking the conductor resistance, and the discharge method by comparison with a known capacity for determining the electrostatic capacity of insulated wires. No mention is made of the potential method for comparing resistances, or of the use of Sir W. Thomson's slides, which are, very late in the day, becoming well known and more frequently used than any other means for comparing and determining the capacity of cables.

On page 59 the author in his description of the manner of finding the "constant" of the galvanometer employed omits to include both the battery resistance and the combined resistance of the galvanometer and shunt in the amount of resistance in circuit, which is usually done. We find also stated on page 69 that if, when testing cables, sudden kicks are observed, "they may be taken as an almost sure indication that the wire or cable has an incipient fault." This inference is not necessarily correct, as the same effects are more frequently the result of defective battery or bad contacts.

The diagrams are simple and easily understood; the illustrations, on the other hand, have a want of clearness which does not recommend the process employed for their production, especially so where good definition is necessary.

The Elements of Dynamic Electricity and Magnetism. By PHILIP ATKINSON. (London: Crosby Lockwood and Son. 1891.)

But for one or two slips of a practical character this is a very fair elementary handbook, but it contains nothing that has not been better written elsewhere. No originality is aimed at, and the apparatus described is chiefly American. In discussing batteries the author remarks in italics that "the practical rule is to *make the internal resistance of the battery equal to the external resistance to be overcome.*" We were quite prepared, after this, to find that it recorded that the efficiency of a motor cannot be more than 50 per cent., but did not discover it; though an equally common and old-fashioned error appears in a section on magnetic lag, which, curiously enough, comes immediately after a reproduction of S. P. Thompson's diagram explaining the true theory of the lead of the brushes by armature reaction.

Arithmetical Physics. Book E. Part II.A. By C. J. WOODWARD, Municipal Technical School, Birmingham. (London: Simpkin, Marshall, Hamilton, Kent, and Co. 1891.)

About one-half of this book is composed of examination questions selected from the papers of the Science and Art Department. Two-thirds or more of the remainder consist of questions which assume that the student has burdened his memory with electro-chemical equivalents, &c., and which ignore the corrections which have to be made in practice. The following is an example:—"A battery of 6 cells gives a current of 2 amperes. Required the weight of zinc in grammes consumed in each cell of the battery per hour." The remainder of the book consists of "lessons" of a very feeble character.

The Wire and the Wave. By J. MUNRO. (London: The Religious Tract Society.)

This is a story for boys, and contains an interesting account of cable work, mixed up with more or less well-known cable stories, adventures, and love-making. The story, says the author in the preface, "is founded on this attractive mode of life, which combines the practice of electrical science with the delights of travel and adventure." This is all very well, but is it right to lead boys to suppose that this is a fair description of this "mode of life"?

Condensed Mechanics. By W. G. CRAWFORD HUGHES. (London: Crosby Lockwood and Son. 1891.)

This is a cram book, pretending to give formulæ, rules, tables, &c., for the use of engineering students, but really intended to enable them to pass certain examinations. The process of condensation seems to consist in the omission of descriptive or explanatory matter. The bulk of the book is occupied by half worked-out examples, without any hints as to the reasons.

Electricity and its Recent Applications. By EDWARD TREVERT. (Lynn, Mass.: Bubier Publishing Company. London: Gay and Bird. 1891.)

A collection of descriptions of electrical apparatus and machinery has been made by the author from technical journals, and these have been interspersed with directions to amateurs for constructing motors, &c. There is little coherence about the book, and the details are not so clearly given as most amateurs would wish.

Kalender für Electrotechniker. F. UPPENBORN. Ninth year, 1892. (Munich and Leipzic: R. Oldenburg.)

This excellent annual maintains its high character. It is full of useful tables, formulæ, and memoranda. No allusion is made to the *drehstrom* system, and too little attention is given to ordinary commercial measuring instruments. We have no book of the kind in the English language.

THE DETERMINATION OF CURRENTS IN ABSOLUTE ELECTRO-MAGNETIC MEASURE.

BY G. F. C. SEARLE, M.A.

(*Continued from page 35.*)

§ 32. **Magnetic Force due to an Element.**—From what has been said above it will readily be suspected that the magnetic force due to an element of a current is really indeterminate. We are, however, able to state a law for the magnetic force due to an element which, when all the elements of a closed circuit are taken account of, will give an absolutely correct result. Suppose now that the magnetic induction is produced by a single pole of strength, m, placed at a distance, r, from the element, ds, of the current. Let the angle between r and the direction of the element of the current be θ. The value of the magnetic induction at ds is $\mathsf{B} = m/r^2$, and its direction is along r. Hence, according to the principles enunciated in the last paragraph, the force experienced by ds is $\mathsf{B}ids\sin\theta$ or $mids\sin\theta/r^2$. If the element of current and the pole are placed as in Fig. 34, both ds and m being in the plane of the paper, then it easily follows from the rule given in § 31 that the force experienced by ds is perpendicular to the paper and towards the reader. But by the equality of Action and Reaction the action of the element upon the pole must be an equal and opposite force *applied at* ds (not at m).

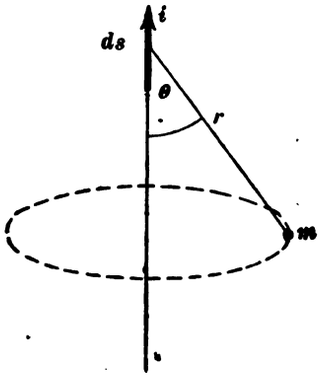

FIG. 34.

Without altering the system of forces in any way we can apply at m a pair of equal and opposite forces at right angles to the paper. By taking the one of these which points towards the reader in conjunction with the original force at ds, we see that the action is equivalent to a force $mids\sin\theta/r^2$ *applied at* m in the direction away from the reader, together with the couple produced by the pair of forces $mids\sin\theta/r^2$ applied to the ends of the radius r. The moment of the couple is therefore $mids\sin\theta/r$. Its axis (see § 6) is in the plane of r and ds at right angles to r, and points towards the direction *from* which the current is proceeding. Let the angle subtended by ds at m be $d\psi$, then it is very easily seen that $r\,d\psi = ds\sin\theta$, so that $d\psi = ds\sin\theta/r$.

Thus the moment of the couple is $mid\psi$ and its axis is in the plane of the angle $d\psi$. Now let a straight line, one of whose ends is fixed at the pole m, travel round the *closed* circuit of which ds forms part, thus tracing out a cone. About m as centre describe a sphere of radius im cutting the cone in a *closed* curve. This curve is clearly everywhere at right angles to the generating lines of the cone. The length of this curve intercepted by the two radii from m to the extremities of ds is $mid\psi$, and the direction of this intercept is at right angles to r. Hence the intercept represents in direction and magnitude the couple due to the element ds. Taking account of all the elements the couples due to them will be represented in direction and magnitude by the corresponding elements of the auxiliary curve. Since this curve is *closed*, the resultant couple is zero, and the action of the whole circuit upon m reduces to a single force applied *at* m, being the resultant of the set of forces similar to $mids\sin\theta/r^2$ applied *at* m. Hence, as long as we only apply our calculations to closed circuits, we may consider the element ids as producing a force $mids\sin\theta/r^2$ at m at right angles to the plane of r and ds. Or we may say that at a point defined by r and θ the element ids produces a magnetic force equal to $ids\sin\theta/r^2$.

It is clear that exactly the same indeterminateness enters into the specification of the magnetic field produced by an element of a current as in the case of the action of a magnetic field upon an element. But so long as we deal only with closed circuits we can calculate the magnetic field quite correctly from the expression $ids\sin\theta/r^2$. This proposition can be proved directly as follows: Give the pole m a small displacement x *in the direction of* the resultant magnetic force H due to the closed current. The work spent upon m during the motion is $m\mathsf{H}x$ ergs. We can also calculate the work spent from the expression $m.i.$ (change of solid angle subtended by circuit), see §§ 19, 20 and 30. The change of solid angle will be the same as if the whole circuit had been given a pure translation through a distance x, the pole meanwhile remaining stationary. When the element ds moves over the distance x it will sweep out a small area; we have to find the solid angle subtended by this area at m. Let θ be the angle between ds and r, ϕ the angle between the direction of x and the normal to the plane of r and ds. The projection of x upon this normal is $x\cos\phi$, so that the projection of the area swept out by ds upon the plane through ds and the normal just mentioned is $ds.\cos\phi$. The angle between this last plane and r is θ, so that the solid angle subtended at m is $ds.x\cos\phi\sin\theta/r^2$. The whole work extended during the motion is therefore $mix\int\frac{\cos\phi\sin\theta\,ds}{r^2}$ ergs, the integration extending all round the closed circuit. Hence $\mathsf{H} = i\int\frac{\cos\phi\sin\theta\,ds}{r^2}$. If we had attributed to each element a magnetic force $ids\sin\theta/r^2$ at right angles to the plane of r and ds, the resolved part of this, in the direction of x, and therefore also in the direction of H, would have been $\cos\phi.ids\sin\theta/r^2$. Thus the resultant magnetic force would have had the value $i\int\frac{\cos\phi\sin\theta\,ds}{r^2}$, the same result as before.

The complete investigation of the possible laws of action of an element (of which the law, represented by $ids\sin\theta/r^2$, is only one) is difficult and unsuited to the present series of articles. But I hope that I have said enough to indicate the class of difficulties which arise when we attempt to resolve a current into "elements."

§ 33. **Circular Conductor.**—In § 26 we found the magnetic force due to a circular coil at any point on its axis, by finding the differential coefficient of the solid angle subtended by the coil. We will now investigate the same subject by the help of the formula we have just obtained. Let a be the radius of the coil, x the distance from the centre of the coil of the point P on the axis at which the magnetic force is to be found.

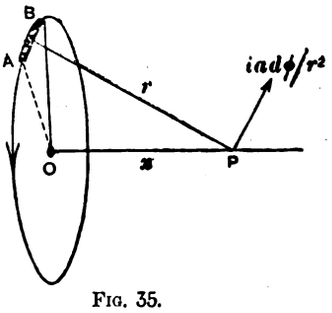

FIG. 35.

Let A B (Fig. 35) be a small portion of the circuit subtending an angle $d\phi$ at the centre O. The length of A B is, therefore, $a\,d\phi$. The radius A P is at right angles to the element A B, so that $\sin\theta = 1$ in this case. The magnetic force at P due to A B is then $i\,a\,d\phi/r^2$ at right angles to A P, and in the plane A O P. Resolving this along the axis we obtain $\frac{i\,a\,d\phi}{r}\times\frac{a}{r}$. The part resolved perpendicular to the axis is cancelled by the effect of the element diametrically opposite to A B. Thus, the resultant magnetic force is along the axis. Adding together the effects of all the elements, we

Digitized by Google

find for the magnetic force $F = \frac{i a^2 . 2\pi}{r^3}$. But $r^2 = x^2 + a^2$, so that $F = \frac{2\pi a^2}{(a^2+x^2)^{\frac{3}{2}}} i$, the same expression as we obtained in § 26. If we had taken P at the centre of the circle, then the magnetic force due to the element $a\,d\phi$ would have been along the axis, and equal to $i\,a\,d\phi/a^2 = i\,d\phi/a$. If we make the radius of the circle one centimetre, and take a length of the current equal to the radius, then the magnetic force produced at the centre by this portion is simply i. We might accordingly *define* the unit current to be that current which, when flowing in an arc of wire one centimetre long, bent into the form of a circle of one centimetre radius, produces unit magnetic force at the centre. The promise made in § 23 has now been fulfilled. From the point of view of §§ 31 and 32 this method of definition is very unsatisfactory.

§ 34. **Long Straight Conductor.**—As another example of the formula $i\,d\,s \sin\theta/r^2$ we will find the magnetic force at any point near a long straight wire. We can do this either by direct integration or by a geometrical method. Let P' A P (Fig. 36), be

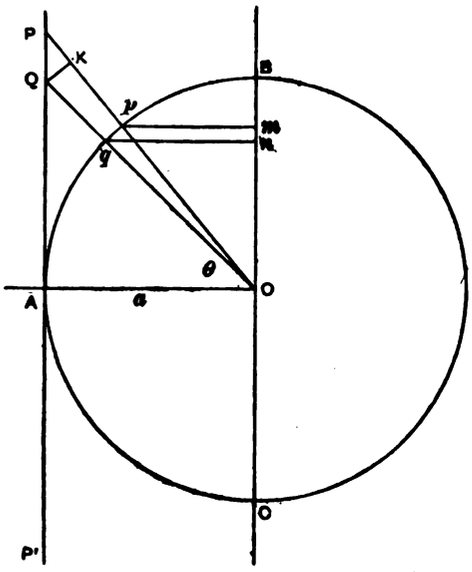

Fig. 36.

the long straight current, O the point at which the magnetic force is to be found. Describe a circle with O at centre touching the wire at A. Let O A = a.

Let P Q be two neighbouring points on the wire, and let O Q = r. Draw Q K perpendicular to O P. Then the magnetic force at O, due to P Q, is $\frac{i\,.\,\text{P Q} \sin \text{Q P O}}{r^2}$ at right angles to the paper. But $\sin \text{Q P O} = \text{Q K}/\text{P Q}$, so that the magnetic force becomes $i\,\text{Q K}/r^2$. If the angle Q O A = θ, then Q K = $r\,d\,\theta$. Thus if F is the magnetic force due to the whole wire $F = 2\int_0^{\frac{\pi}{2}} \frac{i\,d\,\theta}{r}$. But $r = \frac{a}{\cos\theta}$ therefore $F = \frac{2\,i}{a}\int_0^{\frac{\pi}{2}} \cos\theta\,d\,\theta = \frac{2\,i}{a}$.

We arrive at the same result geometrically as follows :—Let O P, O Q cut the circle in p, q. Draw $p\,m$, $q\,n$ perpendicular to the diameter B O C, which is parallel to the wire. Then, by easy geometry $m\,n/p\,q = \cos\theta = a/r$.

Again, $p\,q = \text{Q K}\,a/r \qquad \therefore m\,n = \text{Q K}\,a^2/r^2$.

But the magnetic force at O due to P Q is

$$\frac{i\,\text{P Q} \sin \text{Q P K}}{r^2} = i\,\text{Q K}/r^2 = i.m\,n/a^2,$$

adding together the effects of all the elements of the wire we find that $F = i\,\text{B C}/a^2 = 2\,i\,a$.

We have thus found the same expression as we obtained in § 25 from the principle that the work done in taking a unit magnetic pole round a closed path is 4 π times the current flowing through the space enclosed by the path.

(To be continued.)

THE HEATING OF CONDUCTORS BY ELECTRIC CURRENTS.

The heating of wires by electric currents is a very important subject, which has from time to time received the attention of theoretical writers and of experimentalists. The general law that the current required to maintain wires at a constant temperature varied as their diameter raised to the power of $\frac{3}{2}$ has been brought forward on many occasions since its enunciation by Prof. G. Forbes at the British Association in 1882. In Mr. Preece's Paper before the Royal Society (read April 3, 1884, *The Electrician*, Vol. XII., p. 518) he gave the results of experiments on fine wires used for lightning protectors. He pointed out that for small wires the current varied more nearly as the diameter than as the diameter $\frac{3}{2}$. In Prof. G. Forbes' Paper, read before the Society of Telegraph Engineers, April 24, 1884, this departure from the law was alluded to (*Journal*, Vol. XIII., p. 236). "My own view of the matter is, that while, of course, radiation is proportional to surface, convection is not so, but is nearly constant for rectilinear wires of different diameters at the same temperatures; and that with thin wires, consequently, convection is the most important factor, but for thick wires radiation proportional to surface is the ruling factor." And, again (p. 242), "My impression is that thin wires lose their heat chiefly by convection when free in the air, but larger masses chiefly by radiation." Experiments were quoted to exemplify this, and calculations were given to show "that Macfarlane's constant does not apply to high temperatures, and that the loss of heat is then much greater than in direct proportion to the temperature." In the discussion which followed Prof. Forbes's Paper, curves* were given, showing that the $d^{\frac{3}{2}}$ law, which may be expressed by $C = d^{\frac{3}{2}} \times a$, where C is the current required to raise a wire to any given temperature, d the diameter, and a a constant.

The values of the constant a for different temperatures were given in a curve marked D, and it was observed that "one or two experiments between 100° and 500°C. would give data for plotting the whole of this curve, and from this the emissivity could be determined for any temperature under red heat The relation between the temperature and the constant is approximately satisfied by the empirical formula—

$$c = d^{\frac{3}{2}} \times 54 \times \sqrt[22]{t^\circ},$$

where t° is the temperature above the surrounding air (at 20°C). The departure from the law with very small wires was clearly shown by Mr. Preece's experiments, where a wire of 8 mils took a current of 3·85 amperes to raise it to a dull red heat instead of 3·35."

In the *Electrician*, Vol. XII., p. 541, a very interesting communication from Mr. J. T. Bottomley, commenting on Mr. Preece's work, was published. After discussing the theory of the thermal conditions, he says :—

For round wires of small diameter I have found very much larger emissivity than Macfarlane's $\frac{1}{10000}$th, and, as said above, greater emissivity the smaller the wire. I have obtained different values for wires of different sizes, and for a small wire a numeric as high as about $\frac{1}{100}$th at a temperature of about 70°C.

I do not know that this is to be wondered at, though it certainly was unexpected when we consider the matter in connection with some of the experiments of Aitken on the now celebrated "dark plane," showing the disturbance produced in the air in the neighbourhood of a heated wire.

The result of the whole is that a small wire will lose heat much more rapidly than a large wire under similar circumstances; and I should expect that it would require currents greater for small wires and smaller for large wires than corresponds to proportionality to $d\sqrt{d}$ to maintain the same temperature in them.

P.S.—To avoid misconception I wish to remark that up to the present time I have only experimented at temperatures very much lower than those used by Mr. Preece. I have not yet gone higher than 80° or 85° Centigrade. It is to be noticed that at very high temperatures, such as dull red heat or the fusion temperature of platinum, the separate effects of radiation and of convection, which are included in the theories of Newton and of Fourier under what has been called emissivity in my letter, may hold relations to each other and to the whole phenomenon very different from those which they hold at low temperatures. Thus it is quite possible that at very high temperatures, where radiation becomes predominant, the emissivity for small and for large wires may approximate to be the same. This would correspond to what Mr. Preece has found, though, of course, the subject will require investigation.

* The numbers indicating the ordinates in amperes were misprinted. They should read regularly upwards—5, 10, 15, 20, 25, 30.

Digitized by Google

The subject was taken up by Mr. A. Kennelly in 1889, and was most thoroughly examined by him, and a large number of experiments on a large and practical scale were carried out. His Paper, read before the Edison Convention in August, 1889, was published in full in *The Electrician*, Vol. XXIV., p. 142, &c. Nothing of importance has been published since until the reading of a Paper bearing the names of Prof. Ayrton and H. Kilgour before the Royal Society on November 19th last. This Paper deals with "The Thermal Emissivity of Thin Wires in Air." Mr. Kennelly did not pay special attention to thin wires, but his observations include wires from 134·5 to 35·6 mils (about 10 to 20 S.W.G.). The total emissivity of these was observed and curves were given (*The Electrician*, Vol. XXIV., p. 171) not only of the total emissivity, but of the two components, viz., convection and radiation. These two factors are not separated in the abstract of the recent Royal Society Paper. The wires were enclosed in a water-jacket cylinder, the internal diameter of which is not given. It is well known that the temperature of open-resistance coils used for absorbing energy in testing dynamos or regulating arc lamps, is much greater when the axis of the coil is vertical than when it is horizontal; the difference, which was fully discussed by Mr. Kennelly, being due to convection currents of air. It is true that voltmeters, fuses, and some telegraph protectors are more or less enclosed, and such enclosures probably modify convection currents. But they do not stop them, as is demonstrated by the fluttering of a Cardew voltmeter when the wires are vertical. The diameter of the tube in these experiments, or the dimensions of the enclosing chamber in the case of a voltmeter or a fuse, must considerably modify the convection currents, and they will be affected considerably by the temperature of the walls of the chamber. In a Cardew voltmeter the tube is allowed to attain a steady temperature, being heated by the wires; in these experiments it was kept at a constant temperature, which is not given in the abstract. Under these circumstances it does not appear that the results, which are carried to six significant figures, can be generally applied, nor can conclusions as to the emissivity of wires of an inch or more in diameter be safely drawn from calculations based on the behaviour of wires not exceeding 14 mils. The abstract is not full enough to justify further criticism, but it seems that room has been left for further research. The curves which are alluded to were not published with the abstract, but the table is stated to have been drawn up from them. The construction of tables from curves being, as a rule, a reversible process, we have plotted diameters against emissivities, and expected to get something resembling a "family" of rectangular hyperbolas. These would be isothermal lines, and from them emissivities could be plotted against temperatures, as has been done by Mr. Kennelly. But the table yields a set of curves with a decided "hump" at 8 mils, decreasing a little at higher temperatures. In other respects also the curves yielded by plotting this table are not sufficiently satisfactory to be worth while reproducing, and we are inclined to think that some error must have crept into the calculations, or that some peculiar disturbances were present during the experiments. It was evident, therefore, in 1884 that the emissivity depended both on the temperature and on the diameter of the wire. But the variation of emissivity with the diameter being entirely due to convection, no experiments in which convection currents are not considered separately from radiation can be said to deal thoroughly with the effect of decreasing the diameter of the wires

THE THERMAL EMISSIVITY OF THIN WIRES IN AIR.*

BY W. E. AYRTON, F.R.S., AND H. KILGOUR.

In 1884 it was observed experimentally that whereas the electric current required to maintain a *thick* wire of given material, under given conditions, at a given temperature, was approximately proportional to the diameter of the wire raised to the power three halves, the current was more nearly proportional to the first power of the diameter if the wire were *thin*. When this difference in the behaviour of a thick and thin wire was first noticed it was regarded as being quite unexpected. But, as pointed out by one of us in the course of a discussion at a meeting of the Royal Society, the unexpected character of the result was due to people having assumed that the loss of heat from radiation and convection per square centimetre of surface per 1deg. excess temperature was a constant, and independent of the size and shape of the cooling body.

The very valuable investigations that have been made on emissivity by Mr. Macfarlane, Prof. Tait, Mr. Crookes, Mr. J. T. Bottomley, and by Mr. Schleiermacher, had for their object the determination of the variation of the emissivity with changes of the surface and with change in the density of the gas surrounding the cooling body; but it was not part of these investigations to determine the change in the emissivity that is produced by change in the shape and size of the cooling body. Indeed, so little has been the attention devoted to the very large change that can be brought about in the value of the emissivity by simply changing the dimensions of the cooling body, that in Prof. Everett's very valuable book of Units and Physical Constants the absolute results obtained by Mr. Macfarlane are given as the "results of experiments on the loss of heat from blackened and polished copper in air at atmospheric pressure," and no reference is made either to the shape or to the size of the cooling body.

[November 19, 1891. Since this Paper was sent into the Royal Society a new edition of this book has appeared; and, in consequence of a suggestion made to Prof. Everett the word "balls" has been added after the words "copper" in the new edition, as well as the following paragraph:—

Influence of Size.

"According to Prof. Ayrton, who quotes a table in 'Box on Heat,' the coefficient of emission increases as the size of the emitting body diminishes, and for a blackened sphere of radius r centimes may be stated

$$\cdot0004928 + \frac{\cdot0003609}{r}$$

"The value of r in Macfarlane's experiments was 2."]

The laws which govern the loss of heat from thin cylindrical conductors have not only considerable scientific interest in showing how the shape of a body affects the convection currents, but they are of especial importance to the electrical engineer in connection with glow-lamps, hot-wire voltmeters, fuses, &c. We, therefore, thought it desirable to ascertain the way in which the law of cooling for thick wires, which involved the diameter raised to the power three halves passed into the law for the cooling of thin wires, involving only the first power of the diameter. For this object, the investigation described in the Paper was commenced at the beginning of 1888, and the emissivity was measured of nine platinum wires, having the diameters of 1·2, 2·0, 2·9, 4·0, 6 0, 8·1, 9·3, 11·1, and 14 mils, or thousandths of an inch.

Suspecting that some of the published results concerning the currents required to fuse wires had been much influenced by the cooling action of the blocks to which the ends of the wires were attached, we started by making a calculation of the length necessary to give to our wires, so that the loss of heat by conduction should not introduce any important error into the determination of the emissivity. To do this it was necessary to calculate the distribution of temperature along a wire through which a steady current was flowing and from which heat was lost by radiation, convection, and conduction; and it was further necessary to improve on the calculation one of us had published on this subject in *The Electrician* for 1879, by taking into account the fact that the emissivity, as well as the thermal and electric conducting power, of the wire differed at different points in consequence of the difference of temperature.

Until we had completed the experiments described in this Paper we could, of course, only employ in this calculation values that we had guessed at as being something near the truth for the emissivity of platinum wire for different diameters and at different temperatures. Hence, after the completion of the experiments, we took up the mathematical investigation again, substituting for the emissivity such a function of the diameter of the wire and the temperature of the point as we had experimentally found it to be. Section IV. of the Paper contains the investigation by which we finally arrived at the calculated distribution of temperature along the wire, and we have to express our sincere thanks to Prof. Henrici; (whom we consulted as to the best method of practically solving the rather complex differential equation arrived at) for the warm interest that he has taken in the mathematical treatment of the subject, and for the many suggestions which he has made, and which have enabled us to arrive at the mathematical solution given in the Paper.

Each wire to be tested was stretched along the axis of a water-jacketed cylinder 32·5cm. long, the inner surface of which was blackened and kept at a constant temperature by a stream of water flowing through the jacket. The rate at which heat was lost by any one of the wires was measured by the product of the current passing through it into the potential difference maintained between its

The wire of 4 mils diameter is omitted from the table, as the experiments showed that its specific resistance was much greater, its temperature coefficient much smaller, and its emissivity much smaller than if it had been of platinum. This piece of wire probably, therefore, contained iridium or silver.

ends, while the ratio of the potential difference to the current gave the resistance of the wire, and, therefore, its temperature. Experiments were in this way made with various currents flowing through each of the nine wires.

As the variation of resistance with temperature is known to vary with different specimens of platinum, experiments were separately made to determine the actual law of variation of resistance with temperature up to 300°C. for each piece of wire that had been employed in the emissivity experiments.

In this later determination various thermometers were used, and the subsequent comparison of these thermometers with a Kew standard thermometer involved a vast amount of labour, from the fact that it is or at any rate was not possible three years ago, to purchase from the Kew Observatory a standard thermometer reading from, say, 200deg. to 300°C., with a short wide chamber at the base in which the mercury expanded below 200°C. All that could be obtained was a long thermometer which had been carefully tested between 0deg. and 100°C., and the remainder of whose tube had been simply calibrated for uniformity of bore. The consequence was that when we desired to compare one of our thermometers reading, say, from 200deg. to 300°C., with the Kew standard, their bulbs were very far apart when both were immersed in the oil-bath, and with the tops of the mercury columns just above the surface of the oil. A short description is given in the Paper of the devices employed to overcome this difficulty and which enables an accurate comparison to be made between the thermometers.

On examining the curves accompanying the complete Paper which show the emissivity for each temperature of the nine wires, we see that :—

1. For any temperature the emissivity is the higher the finer the wire.

2. For each wire the emissivity increases with the temperature, and the rate of increase is the greater the finer the wire. For the finest wire the rate of increase of emissivity with temperature is very striking.

3. Hence, the effect of surface on the total loss of heat (by radiation and convection) per second, per square centimetre, per 1°C. excess temperature, increases as the temperature rises.

On comparing the loss of heat from the wire of 1·2 mils diameter when at 300° C. with that from the wire of 6 mils diameter when at 15° C., both being in an enclosure at 10° C., we see that the former loses per square centimetre of surface per second not

$$\frac{300-10}{15-10}, \text{ or } 58 \text{ times}$$

as much heat as the latter, as it would if the emissivity were the same ; but, instead,

$$60 \times 58, \text{ or } 3{,}480 \text{ times}$$

as much heat ; arising from the fact that the emissivity, that is, the number of calories (gramme C.°) lost per second per square centimetre of surface per 1° C. excess temperature of the 1·2-mil wire at 300° C., being 60 times as great as that of the 6-mil wire at 15°, the latter varying very rapidly with the temperature near 15° C.

From the curves the above table has been drawn up, giving the emissivities of the various wires at eight useful temperatures.

We find that the emissivity of platinum wires of different diameters at the same temperature can be very fairly expressed by a constant plus a constant into the reciprocal of the diameter of the wire. For example, we find that

At 100° C. $e = 0{\cdot}0010360 + 0{\cdot}0120776 d^{-1}$ . . . . . (1),
,, 200 ,, $e = 0{\cdot}0011113 + 0{\cdot}0143028 d^{-1}$ . . . . . (2),
,, 300 ,, $e = 0{\cdot}0011353 + 0{\cdot}016084\ d^{-1}$ . . . . . (3),

where d is the diameter of the wire in mils, or thousandths of an inch.

The emissivities have been calculated in calories lost per second per square *centimetre* per 1° C. excess temperature, in order that they may be compared with the emissivities obtained by other experimenters ; but we prefer to speak of the diameters of the wires in *mils*, since a wire of 1 mil is about the finest that is drawn commercially. Hence the statement that the diameters of wires are 1, 2, or 3 mils is more suggestive to an engineer than saying that they are 0·0254, 0·0508, or 0·0762 millimetre.

The statement, not unfrequently made, that the current required to maintain a wire of a given material at a given temperature above that of the surrounding envelope is proportional to the diameter of the wire raised to the power three halves is equivalent to stating that the emissivity is independent of the diameter. Now from the three formulæ (1), (2), (3), given above for e, we may conclude—

That for a temperature of 100°C. the value of d in the formula

$$e = 0{\cdot}0010360 + 0{\cdot}0120776\ d^{-1}$$

must be something like 220 mils, or 5·6mm., in order that the neglect of the second term may not make an error in e of more than 5 per cent., and something like 1·15 inches, or 29·3mm., if the error is not to exceed 1 per cent.;

That for a temperature of 200°C. the value of d in the formula

$$e = 0{\cdot}0011113 + 0{\cdot}0143028\ d^{-1}$$

must be something like 244 mils, or 6·2mm., in order that the neglect of the second term may not make an error in e of more than 5 per cent., and something like 1·28 inches, or 32·5mm. if the error is not to exceed 1 per cent. ;

And that for a temperature of 300°C. the value of d in the formula

$$e = 0{\cdot}0011353 + 0{\cdot}016084 d^{-1}$$

must be something like 267 mils, or 6·8mm., in order that the neglect of the second term may not make an error in e of more than 5 per cent., and something like 1·39 inches, or 35·3mm., if the error is not to exceed 1 per cent.

Generally, then, we may conclude that to assume that the emissivity is a constant for wires whose diameters vary from a small value up to 1in. is to make a large error in the case of the greater number of the wires, and an error of hundreds per cent. in the case of some of them.

Using the formula (3) which we have arrived at for determining the emissivity of platinum wires of different diameters at 300°C., it follows that to maintain a platinum wire 0·75 mil in diameter at 300°C. would require a current density of 331,000 amperes per square inch ; and, if the emissivity of a copper wire of the same diameter and at the same temperature may be taken as being the same, it follows that to maintain a copper wire 0·75 mil in diameter at 300°C. would require a current density of 790,000 amperes per square inch.

ELECTRIC LIGHTING AND TRACTION NOTICES.

The time for giving official notice in the *London Gazette* of all Private Bills that will be brought forward next Session, and of all Provisional Orders for which application is about to be made to the Board of Trade, has now expired. From the notices thus given it is found that the total number of Private Bills proposed to be introduced into Parliament next year is only 188, and the total number of Provisional Orders that will be applied for is 69. Of the Private Bills no fewer than 24 relate directly to London, among which are a projected railway from Waterloo to the City, a line from Waterloo to Baker-street, and another projected line from Charing-cross to St. Pancras and Hampstead. The existing or authorised electrical railway companies are also promoting extensions from King William-street to Islington, and from the Mansion House to Liverpool-street ; whilst other lines are proposed from Finsbury Park Station to the City, and from the City to Epping Forest.

Digitized by Google

Of the Provisional Orders 34 relate to electric lighting; and of the electric lighting Orders 11 are for certain areas in London. In November, 1889, no less than 159 Orders were applied for, and last November the total was 76, of which 17 referred to the metropolis. The number of applications for Provisional Orders tends, therefore, to vanishing point. On the other hand, electric traction notices are, as might be expected, more numerous than was the case last year, when only nine were issued against 15 this year.

Corporation of Newcastle-on-Tyne.	Construction of tramways in Elswick and elsewhere. The exclusive right to use animal, electric or other mechanical power.
Corporation of Newport.	Construction of tramways, with use of electrical or other power.
Liverpool United Tramways and Omnibus Company.	To construct various tramways, to use electric or other power.
Somerton, Kimpton, Mandeville, Castle Cary, and Evercreech Tramways.	To construct various tramways, to use electrical or other motive power.
Blackpool, St. Anne's, and Lytham Tramways.	To make agreements with the Blackpool Electric Tramways Company, and use electricity or other motive power.
Liverpool Overhead Railway Company.	Extension of time. Construction of additional works. Use of electricity.

SECONDARY BATTERIES.

BY G. H. ROBERTSON, F.C.S., ASSOC. INST. EL. ENG.

Introduction.

The secondary, or, as it should rather be called, the reversible battery, dates practically from the discovery that electric currents could be produced by the agency of chemical actions, and its development progressed with the increase of our knowledge of the laws which govern electrolysis.

In the year 1800 Volta discovered that a current could be obtained through chemical agency, and in the following year Gautherot observed that when electrodes of silver or platinum wire were used for the electrolysis of acidulated water, they gave a current in the reverse direction to that in which the battery current had been passing, if they were connected through a galvanometer directly the battery was removed.

These inverse or polarisation currents as they were called, were a source of great perplexity; and although much work was done on the subject, and many theories were started to account for their origin by Volta, Ritter, Marianini, Becquerel, Grotthus, and others, no satisfactory explanation was forthcoming until Faraday set the whole theory of electrolysis on a firm basis in his Papers communicated to the Royal Society between June, 1833, and March, 1834.

Although many apparent contradictions have been found to Faraday's well-known simple laws, and the precise mode in which a current is conveyed through an electrolyte is still under discussion; yet his work showed that chemical and electrical energy were mutually convertible, and that the so-called polarisation currents were due to the reversible nature of the chemical changes caused by the passage of the primary current.

The way was thus cleared for improvements in batteries in general, and very many have been brought out; but it was not till much later when Faraday's other great discovery of the laws relating to the conversion of mechanical into electrical energy bore fruit, and provided a cheap source of electricity, that much attention was paid to reversible batteries.

In the course of his experiments on electrolysis he nearly anticipated Planté's discovery of the peroxide of lead—lead couple; for in the case of the electrolysis of a solution of acetate of lead he noticed that on the passage of the current peroxide of lead was formed on the one plate and lead on the other.

In 1843 Grove invented his gas battery, and in 1852 Dr. C. W. Siemens constructed a reversible battery, using carbon plates as his electrodes, and a strong solution of acetate of lead as his electrolyte.

In 1859 Planté made a number of experiments with copper, silver, tin, lead, aluminium, iron, zinc, gold, and platinum voltameters to determine which was the best couple to use for a reversible battery, and decided on the use of lead plates in dilute sulphuric acid, because in discharge both plates were active; that is, not only did the peroxide of lead plate combine with hydrogen, but the reduced metallic lead combined with oxygen; thus the E.M.F. of the cell was due to chemical actions occurring on both plates. In those days the action of the cell was ascribed solely to the decomposition of water, and the effect of the sulphuric acid was left out of account.

In 1872 Planté improved the "formation" of his cell by bringing out the process for alternate reversals of the current; and in the decade which followed, with the improvement of the dynamo, and the consequent growth of electrical engineering, the need for some means of storing electrical energy arose, and the reversible battery passed from the laboratory into commercial use.

Reversible Batteries.

In 1880 M. Camille Faure invented his cell, in which the electrodes consisted of lead plates, smeared with pastes of red lead and litharge respectively, and covered with a protecting layer of felt. On charging the red lead was oxidised to peroxide of lead, and the litharge was reduced to metallic lead, thus quickly forming a Planté couple of considerable storage capacity.

The same impetus in electrical work which gave rise to the Faure battery led also to the introduction of several other types of reversible batteries ; and as I have been able to obtain very little information about them, I will deal with them and their developments now, before proceeding with the numerous improvements in the two lead types.

Profs. Thomson and Houston have tried electrodes of copper in sulphate of zinc solution ; the plates were laid horizontally, so that the relative weights of the sulphate of zinc and sulphate of copper formed in the working might prevent their mixing too readily. The E.M.F. was the same as that of the Daniell.

M. d'Arsonval modified this battery by making one electrode of lead and the other of zinc, the solution being sulphate of zinc as before. The lead plate forms the positive, and becomes coated with peroxide during charge. According to Miesler the E.M.F. of this arrangement is 2·13 volts.

Sutton tried copper and lead plates in copper sulphate; the E.M.F. being 1·22 volt.

In 1886 M. Dezmazures brought out a modification of the Lalande and Chaperon cell, the solid copper plate being replaced by a porous one made by first reducing copper oxide electrically, and then compressing the fine metallic dust so obtained into plates.* The other electrode was made of tinned iron gauze, and the solution was potassium zincate. The E.M.F. is only about one volt, but the cells are light, and a battery of this description gave satisfaction as a source of motive power at the trials on the French torpedo boat, "La Gymnote," at Toulon. Recently this battery has been tried for traction work in Philadelphia, under the name of the Waddell-Entz accumulator.† In the American form of the battery the copper plates are made of a sort of wire rope, formed of a stout wire core braided over in opposite directions with two layers of wire of different thicknesses, the finest outside. This is again braided with asbestos, or some similar material, which retains and protects the copper oxide formed by electrolysis. The weight of the battery is given as from 55lb. to 60lb. per horse-power stored.

Lead Reversible Batteries.

On the introduction of the Faure cell into England in 1881, great hopes were entertained of it, and the modification in the manufacture of the plates seems almost to have been regarded as constituting a fresh type of cell ; whereas, since the couple was identical, the chemical reactions were the same as in the Planté cell, and any defect due to these would be common to both. As lead reversible batteries cannot be said to have completely realised the hopes then entertained, it is important to discover whether the non-fulfilment is due to causes which can be remedied by improved processes of manufacture, or whether they arise from the chemical reactions occurring in the working of the cell, and are to be met rather by improved treatment after than during construction. I have thought, therefore, that a Paper containing a summary of some of the principal improvements which have been introduced in the construction of the cells, and an account of some experiments dealing with the chemistry of the subject, might lead to some useful discussion.

From a comparison of the two cells made by M. Achard it appears that on its introduction the internal resistance of the Faure was much higher than that of the former, while the Planté cell took longer to form, and was heavier than the Faure. The time required for formation and the weight of the cell were the chief drawbacks to the Planté process of manufacture ; the Faure method had the disadvantage that the applied paste was liable to separate from its support. The remedying of these defects, then, has been the principal aim of the improvements which have been brought out in the two types of the lead reversible battery.‡ To give a complete list of these would be quite beyond the scope of this Paper, but they may be summarised as follows :—

I.—Improvements in the Planté type, *i.e.*, that in which the peroxide of lead and spongy lead are formed direct from metallic lead by electrolysis.

In this type, since both the weight of the plate and the time required for "formation" can be shortened by making the plate porous, and thus exposing more surface to the action of the acid and charging current, obtaining porosity has been the chief aim of inventors. The methods which have been suggested from time to time may be classified under three headings :—

A. Chemical.—The plates are subjected to some "pickling" process, or some special "forming" bath is used.

B. Mechanical.—The plates are made of granulated lead, wire, or some form of finely divided lead.

C. Electrolytic.—(1) The finely divided lead is obtained by the electrolysis of some salt of lead. (2) Some salt of lead is formed into a plate by pressure, or otherwise, and then reduced to metallic lead.

I.—Improvements in the Planté Type.

Chemical Processes.—Planté found that plates of lead which had been steeped for a long time in dilute sulphuric acid, before being submitted to the action of the charging current, "formed" more rapidly than those which had not been so treated, and he also found that "formation" was hastened by heating the cell during the process ; this, however, was difficult in practice.

In 1882, in order to roughen the surface, he pickled the plates for from 24 to 28 hours in a bath composed of nitric acid, diluted with from once to twice its volume of water. The plates were then thoroughly washed, and the formation completed in a bath of dilute sulphuric acid 1 to 10. By this improvement he stated that a capacity, which under the old process took several months to obtain, could be acquired in eight days.

Almost simultaneously, Messrs. Elwell and Parker suggested the use of a mixture of nitric and sulphuric acids as a pickling bath. Since then different baths containing nitric acid in varying proportions have been brought out, and from the earliest times the addition of some salt of the alkalies, such as ammonium, sodium, potassium, or magnesium sulphate to the electrolyte during formation has been suggested as an improvement.

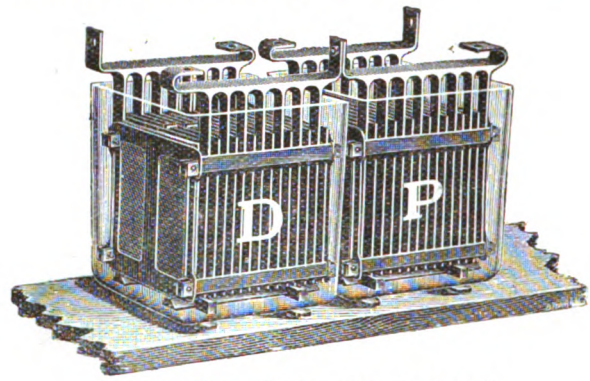

Fig. 1.—Messrs. Drake and Gorham's Cell.

In 1884 Mr. FitzGerald proposed the use of phosphoric acid ; and in the same year Mr. Tribe experimented with plates partially or wholly converted into sulphide, phosphide, or arsenide, prior to "forming" them by electrolysis.

Coming to recent processes, in 1890 Mr. Epstein suggested first boiling the electrodes in a bath containing 1 per cent. nitric acid, 1 per cent. potassium permanganate ; or else, in lieu of the permanganate, 2 per cent. carbonate or sulphate of sodium, or 1 per cent. sulphate of manganese. The plates are dried in air, and then "formed" by the action of the current in an electrolyte containing acetic, phosphoric, or tartaric acid in the proportion of ½ to 2 per cent.

A few months later Dr. Paul Schoop brought out his process for first subjecting the plates to the action of a current of about one-sixth of an ampere per 100 sq. c.m. at 50°F., in a bath composed either of 100 parts by weight ammonium sulphate, 140 parts by weight sulphuric acid (50 deg.), two-thirds one part by weight potassium chlorate ; or else, 100 parts by weight water, 5 parts by weight sodium bisulphate, two-thirds one part by weight potassium chlorate. The treatment is continued for from 36 to 100 hours, according to the depth of the active material required. The formation is completed in ordinary dilute sulphuric acid.

Mechanical Processes.

Messrs. Crompton and Howell's well-known plates, formed by the compression of a specially porous granulated lead, are an instance of this type, and from their great porosity they are capable of a very high rate of discharge.

In Messrs. Drake and Gorham's cell (Fig. 1), both plates are formed of roughened strips of lead, laid horizontally one over the other, and connected by their ends to upright rods. From its

† *The Electrical Engineer*, Vol. VII., No. 23, p. 556.

‡ For an account of the lead batteries on their first introduction into commercial work, and of the early suggestions to replace them, see a Paper by Prof. W. Grylls Adams, F.R.S., read before the Science Society of King's College, October 25, 1881, and published in *The Chemical News*, Vol. XLV., p. 1. In Mr. Niblett's Paper on "Some Recent Improvements in Lead Secondary Batteries," read before the Physical Society of Glasgow University last January, and published in *The Electrical Engineer*, Vol. VII., Nos. 13 to 17, will be found an account of the principal structural improvements which have since been effected.

Digitized by Google

construction this plate is free to expand and contract without injury to itself.

In Mr. Niblett's so-called "solid cell" * the electrodes are separated by porous partitions, and the space between the electrodes and the partitions is filled up with granulated lead. In this cell there is practically no free electrolyte to wash about and spill; it is all absorbed either in the mass of spongy material forming the electrodes or in the porous partitions.

Plates have also been made of compressed lead dust, of wire loosely woven and compressed, as in Reynier's cell; or in the form of rope, as in the Legay cell.

M. Bandsept's plates would appear to be of this type, as they are made of extremely finely pulverised material, which is then compressed into briquettes, and subjected to a forming process. The cell is now in use commercially in Brussels, but very little information can be obtained about it.

Electrolytic Processes.

1. *The Electrolysis of some Lead Salt Solution.*—The acetate of lead has been frequently employed for this purpose since Siemens used it; and another salt that has been the subject of many patents is the chloride of lead. In America last year it was proposed by an Englishman named Currie, to form the electrodes of rods or bars of lead, coated with woven asbestos. These electrodes are then placed as anodes in a bath of zinc chloride, and lead chloride to the required depth is formed on them, while zinc is deposited on the cathodes. On reversing the current, spongy metallic lead is produced on what are now the cathodes, and the zinc goes into solution, being thus used over and over again.

2. *The Reduction of a Plate formed of some Salt of Lead.*—Perhaps more patents have been taken out under this heading than any other. Plates have been formed of the fused chloride, cerussite, or the native carbonate, has been compressed into plates, and in fact any salt of lead, even lead sulphate, which can be got to reduce to metallic lead by the action of the current, has been employed.

In the Laurent-Cely cell the plates are composed of pastilles of specially prepared lead chloride, round which frames of an alloy of lead and antimony are cast. By the action of zinc in very dilute hydrochloric acid, the plates are converted into cellular lead. The plates are then washed in cold water, dried, and the positives converted into litharge by the action of a current of hot-air. The formation is then completed by electrolysis in the usual way.

For this cell it is claimed that the density of the positives is 4·3 to 5, while that of the negatives is only 3 to 3·5. Great storage capacity for weight is also claimed.

II.—Improvements in the Faure Type.

II. Improvements in the Faure type, *i.e.*, that in which the perioxide of lead and spongy lead are formed by electrolysis from some oxide applied to the plates.

As in this class of cell the active material is applied to the electrodes, and not formed from them as in the original Planté cell, it is obviously desirable that the supporting part of the electrode should be light, and not weakened by taking part in the chemical reactions. These requirements have been met in many instances by replacing the solid lead plate by a grid, usually made of an alloy of lead and antimony, since such an alloy is less acted on by the acid, and is much stronger than pure lead.

In the E.P.S. cell the use of an alloy of lead and antimony was abandoned, because if sufficient antimony to obtain a good casting was added, the grid was so hard that it did not yield to the expansion of the paste, which consequently forced itself out of the plate. Lead grids were then employed, but now they have been abandoned for rapid discharge work, and a solid plate has been reverted to.

In the latest form of Mr. Fitz-Gerald's lithanode cell weight is reduced by making the support of a light double frame of copper wire, protected from the action of the acid by dipping it first in soldering fluid, and then in molten lead.

The other improvements fall into two principal divisions:—A. Those which have for their object the retention of the paste on the plate, and they may be classed under four headings. B. Those intended to provide better connection between the support and the active material.

A. The Retention of the Paste.—1. The plate is not perforated, but grooves or recesses are made on the surface; or it is cast with projections from it so as to afford a lodgment for the active material.

The Tudor plate is a familiar instance of this type, which has the advantage that the support gradually gets "formed," and supplies active material to replace that lost in the working of the cell. In the new 1890 pattern E.P.S. plate an early form introduced originally by Swan has been resorted to. The plate is grooved horizontally, as in the Tudor plate, and the ridges between the grooves curve slightly upwards towards the surface of the plate, forming a lodgment for the paste.

2. The support is some form of grid, that is, is perforated with holes as in the old pattern E.P.S. plate and the Julian grid (Fig. 2).

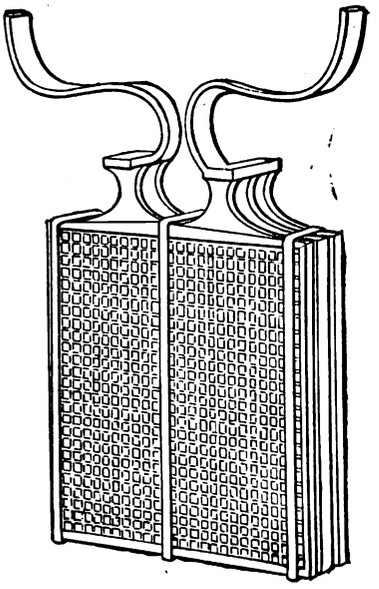

Fig. 2.—Element Consolidated Electric Storage Company

A great many varieties of this form of plate have been suggested, and the apertures have been made by casting the grid in a mould, and by punching. Their form has been cylindrical, barrel-shaped as in Messrs. Drake and Gorham's old positive plates, shaped like two cones joined at the apices, and to give greater security the perforation has been made to expand again just at the junction of the apices.

(To be continued.)

DESCRIPTION OF THE STANDARD VOLT AND AMPERE-METER USED AT THE FERRY WORKS, THAMES DITTON.*

BY CAPTAIN H. R. SANKEY AND F. V. ANDERSEN.

(Concluded from page 95.)

Calibration of Galvanometer.—Fig. 3 shows the connections and general arrangement. A current is established by means of two or three secondary cells through two suitable rheostats, one having a fixed and the other a variable resistance, the latter made of mercury placed in grooves of a wooden trough with two copper slides. The strength of this current is varied by adjusting the mercury rheostat until the fall of potential across the fixed resistance—"A" on the diagram, Fig. 3—the terminals of which are connected with two

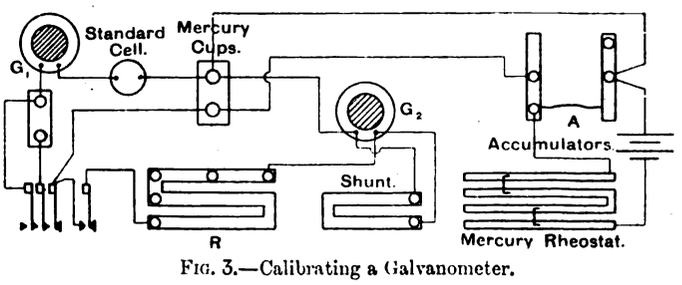

Fig. 3.—Calibrating a Galvanometer.

mercury cups on the instrument table, is equal to the E.M.F. of the standard cell. The balance is effected by placing a standard cell joined in series with a second galvanometer in opposition to the potential difference between the two mercury cups, and adjusting the mercury resistance until no deflection is obtained on the second galvanometer. The galvanometer to be calibrated forms with an adjustable resistance box in series, and generally with a shunt across its terminals, a circuit between the same mercury cups. When no deflection is obtained on the second galvanometer, the fall of potential across the circuit of the galvanometer under calibration is equal to the E.M.F. of the standard cell. Clearly,

* Paper read before the Institution of Electrical Engineers.

therefore, the current in the galvanometer can be easily found by means of the formula,

$$c = \frac{e}{m\,R + G} \quad \ldots\ldots\ldots \quad (5)$$

c = current through galvanometer.
m = multiplying power of shunt on G.
R = resistance in series with G.
G = ,, of galvanometer.

As a practical matter, the values of R based on the use of a certain shunt are calculated beforehand, so that the current shall be 10, 20, 30 . . . . micro-amperes ; and the observations are noted as shown on Table III., which gives the calibration of galvanometer No. 1,588, taken on April 22 last.

In the circuit of the standard cell a key is used which has double contacts, and is connected with a high resistance (about 10,000 ohms) in such a manner that, when the key is depressed half-way, this resistance prevents an injurious current from passing through the cell, whilst, when the key is completely depressed, after the balance has been very nearly established, the resistance is short-circuited, and so the full sensitiveness of the arrangement obtained.

When the potential difference between the mercury cups is equal to the E.M.F. of the standard cell no current passes through the second galvanometer, the spot of which will move visibly for a current of one ten-millionth of an ampere. As the internal resistance of the standard cell plus the resistance of the galvanometer does not exceed 1,600 ohms, a visible deflection is obtained, one way or the other, if the balance is at fault to the extent of $\frac{1}{10^7} \times 1{,}600$, or ·00016 volt, which is about ·011 per cent. of the value of the standard cell.

The mercury varying but little in resistance by temperature, and giving perfect joints with the copper slides, allows of the resistance of the mercury rheostat being adjusted with any desired accuracy, and remaining practically constant when once correctly adjusted. The delicacy of this electrical balance is so great that a movement of 1-64th inch of one of the slides is sufficient to cause a deflection on the second galvanometer.

This balance is tried for each reading when calibrating a galvanometer.

Table III.

Calibration of Galvanometer No. 1588, 22/4, 1891.

Temperature of cell and instruments, 14·5°C.
E.M.F. of cell, e = 1·4386 volts (legal).
Resistance of G = 430·9 ohms ,, (measured).
Resistance of shunt = 47·9 ohms ,, = $\frac{1}{9}$ G.

Current in G $= c = \frac{10^5 e}{R + \cdot 1\,G}$ micro-amperes.

$$\therefore R = \frac{10^5 e}{c} - \cdot 1\,G = \frac{143{,}860}{c} - 43\cdot 1 \text{ legal } \omega \quad \ldots\ldots\ldots \quad (6)$$

170	803·1	384·0	...

From the calibration in Table III. the volt scale was constructed on the white margin immediately below the millimetre scale by simply projecting the points of the readings in column 3 downwards by means of a set square and dividing up the sections into units. The ratios $\frac{\text{difference of current}}{\text{difference of deflection}}$ contained in column 4 of Table III. show that the deflections are fairly proportional to the currents. Some allowance is to be made for inaccuracies in the millimetre scale apart from errors of observation.

The calibration of the ampere galvanometer G_1 and the manufacture of the ampere scale were done in the same manner as here described.

These calibrations have been repeated several times at intervals, besides which frequent calibrations of mean readings have been taken—formulæ 2 and 4 in the preceding.

It has been found that the constants of the two galvanometers have not altered beyond 1-5th per cent. during six months, except on two occasions when the levelling of the instruments had been interfered with.

For purposes like these measurements a D'Arsonval galvanometer should have a glass front to the case, so that the coil is clearly visible, and there should be means of verifying and adjusting the position of the coil in the field. The coil should be wound on a metallic (aluminium) frame, to prevent changes in its shape ; and there should be a torsion head outside the cover, so that the original zero of the coil in the field can be restored without opening or interfering with the instrument.

As a slight set crept into the suspending wires of the two galvanometers used in the apparatus, and as they had no arrangement for restoring the zero, it became necessary to turn the instruments on their bases, as the position of the scales could not be altered. The effect of the shifting was hardly noticeable on one of the instruments, but it caused an alteration in the constant of the other to the extent of 1·2 per cent, and a discrepancy of ·3 per cent. in the proportionality of the scale, which necessitated re-graduating it. An alteration in the constant alone can, of course, at once be balanced by a correction in the resistance used in series with the instrument.

New instruments fulfilling the above conditions are being made.

Main Ampere-Rheostat.—This rheostat, which is marked B on the diagrams, is made of 40 platinoid strips, 6 feet long each, all joined in parallel between two copper terminal bars. The thickness of the strips is ·03 inch ; the total width = 38 inches. The cross-section is 1·14 square inches ; the resistance is ·0010882 legal ohms at 17°C. The total surface of the strips, including the two terminal bars, is 5,854 square inches. When carrying 1,000 amperes 1,088·2 watts are consumed by the rheostat—*i.e.*, power is given off to the atmosphere at the rate of ·186 watt per square inch of surface, which has been found to cause a rise of temperature near the centre of the strips of very nearly 20°C. The rise of temperature in this rheostat has been observed with different currents, and has been found to be proportional to the square of the strength of the current.

The arrangement used for determining the resistance of B is shown on Fig. 2. It will be seen that B is placed in series with another rheostat, A, and with the mercury rheostat previously mentioned, and that the circuit further contains a few secondary cells. The current in this circuit is adjusted by the mercury slide resistance until the fall of potential across resistance A is equal to the E.M.F. of the standard cell, which is ascertained by means of galvanometer G_2 in the manner described previously when the calibration of the galvanometers was dealt with. The deflection is then read on the scale of galvanometer G_1, which is joined (with a resistance box in series) across the terminals of B. The resistance of rheostat A, as well as the value of the deflection on G_1 and of the resistance R in series with it, being known, the necessary data for finding the resistance B are to hand. This resistance is obtained from the formula,

$$B = A/e\,c\,(G_1 + R)^* \quad \ldots\ldots\ldots \quad (7)$$

where e = E.M.F. of standard cell ;
c = the current corresponding to the reading on G_1.

Table IV. contains the results of two determinations of B obtained at different dates.

Table IV.

Determinations of Resistance of Main Ampere-Rheostat.

Date.	Number of experiments.	Resistance of B.	Remarks.
2nd April, 1891.	8	·0010882 (reduced to 17°C)	Currents used through B = 29·63 and 49·36 ampere.
21st July, 1891.	3	·0010869 (reduced to 17°C)	Current through B = 49·04 ampere.

Rheostat A.—As is seen from the preceding part of this Paper, the accuracy with which currents can be measured in the present system depends upon the knowledge of the value of the resistance of this rheostat. Great care was therefore taken in its manufacture and adjustment. It consists of five strips of platinoid, each intended to carry 10 amperes without material warming. The end of each strip is soldered to a massive gun-metal block let into a wooden frame. These blocks have holes drilled in them about $\frac{3}{4}$in. diameter for use as mercury cups. Two heavy strips of gun-metal are let into the frame, one at each end, and there are also holes in these strips opposite the holes in the blocks. The connections are made by thick copper bridge-pieces. By this arrangement the strips can be placed either in series or in parallel, and one or more of the strips can be placed in the circuit.

* For $e/A\,B = c\,(G_1 + R)$.

Digitized by Google

The resistance of each strip is arranged so that the fall of potential across it when a current of about 10 amperes is flowing through it is equal to the E.M.F. of the standard cell.

The absolute resistance of the strips could have varied within certain limits, but it was necessary to adjust the resistance of each to equality with a considerable degree of accuracy. As there was no means of doing this at Thames Ditton, the resistance was taken to the Ordnance Survey, Southampton, about two years ago, and the adjustment made by scraping the strips until their resistances were equal.

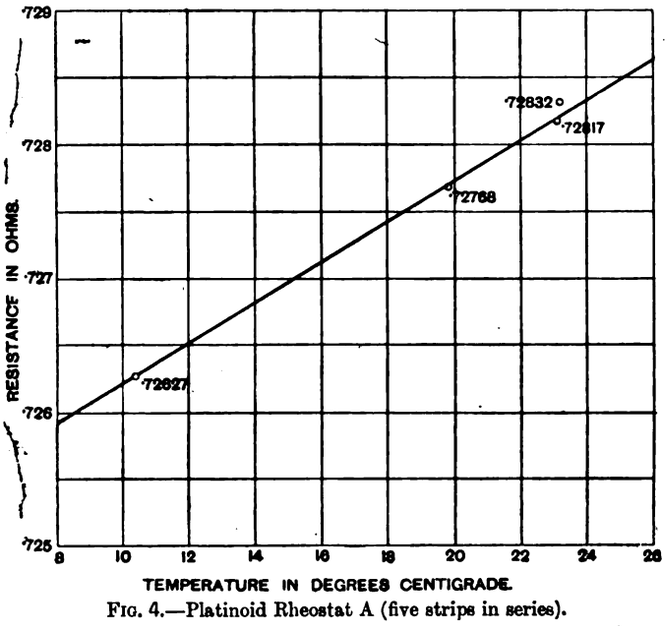

FIG. 4.—Platinoid Rheostat A (five strips in series).

The resistance of the five strips in series was then taken at different temperatures, and as there are special arrangements at Southampton for keeping the temperature of the testing-room constant, the temperature of the platinoid strips could be accurately determined at the time when each resistance test was taken. The results of these tests are given in Fig. 4. The balance was made against the Ordnance Survey standard ohm (legal).

At Thames Ditton the resistance of the strips has been determined from time to time by a direct comparison with the Thames Ditton standard ohm in the manner shown in Fig. 5. It will be

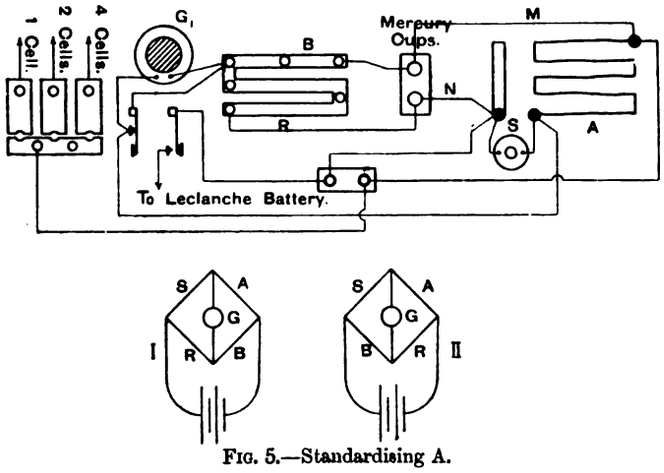

FIG. 5.—Standardising A.

seen that the resistance and the ohm form two arms of a Wheatstone bridge arrangement, and boxes of coils the other two arms, as shown by the two small diagrams I. and II. (Fig. 5). The adjustable resistance R is first placed in one arm, and then in the other, so that the resistance A of the strips is found by the equation,

$$A = S\sqrt{\frac{R_2}{R_1}}. \quad \ldots\ldots\ldots \quad (8)$$

where

S = the resistance of the standard ohm at the given temperature;

R_1 and R_2, the values of the adjustable coils in the first and second measurements respectively.

The only alterations required in the connections in going from the first of the two tests to the second is the changing of the two leads, M and N, in the mercury cups.

It will be observed that by this arrangement no allowance has to be made for leads, and the absolute resistance of the box of coils is immaterial; true proportionality only is required; thus the temperature of the box of coils does not affect the result.

Fig. 4 shows that the resistance of the five platinoid strips rose from ·7262 ohm to ·7280 ohm for a rise in the temperature from 10° to 22°C., which gives a temperature coefficient of ·0207 per cent. per degree Centigrade. At 14·8°C. the value, according to the tests at Southampton, is ·72693. The test at Thames Ditton gave ·72659, leaving a discrepancy of ·047 per cent.

Surface Leakage.—One way of quickly making a test of the state of the instruments is to send a current from the testing cells through the rheostat B, with the connections as in Fig. 2, which, when the instruments are not in use for other purposes, can be done by merely turning on a switch, and read the value of this current on the ampere galvanometer with various constants, altering the resistances in series according to Table I. When this experiment was tried after the instruments had been out of use during the Easter holidays, the galvanometer gave a higher value for the current with constant ·5 than with constant 1, and with constant ·1 still a higher value than with ·5. This discrepancy, which amounted to no less than 3 per cent., was found to be due to surface leakage, which was greater with the higher constant obtained by higher resistance in series. It disappeared completely by a slight rubbing of the top of the resistance boxes with a piece of leather.

The considerable error mentioned was obtained with a current of about 40 amperes, producing a potential difference across the instruments of only about ·043 volt.

DISCUSSION.—AUTHORIZED ABSTRACT.

Mr. GISBERT KAPP said he understood that the platinoid sheets of rheostat A were sometimes used 5 in series (as in Fig. 2 of the Paper) and sometimes 5 in parallel, and he would like to know how the change was effected without introducing unknown resistances.

Prof. AYRTON said he was glad to see that the authors were supporters of the deflectional method of measuring amperes and volts, in preference to the zero method so often adopted. There were several points in the present Paper with which he differed. In the first place he would like to know why galvanometers of comparatively high resistance were used, and why they were wound with copper. For the current measurements, a low resistance instrument would have been decidedly preferable, and both galvanometers ought to have been wound with platinoid. The ampere meter would then require no correction for changes of temperature of the room. He enquired whether any special arrangement had been adopted to make the deflections of the galvanometers proportional to the currents. Putting curved pole pieces on the magnets and allowing the coil to hang freely from the top suspending wire would give the desired result. He thought the authors of the Paper had overstated the range of their amperemeter by giving it as from $\frac{1}{40}$ to 1,100 amperes, for the former current only gave a deflection of about one thousandth of the length of the scale, and therefore could not be measured with any approach to accuracy. Referring to the voltmeter instrument he enquired whether the error introduced by shunting part of the potentiometer P (Fig. 1 of Paper) by the galvanometer and resistance R had been allowed for; in some cases given in Table II., neglecting this would introduce an error of 0·5 per cent. He was of opinion that standard instruments for workshop or factory use should require no constants and no adjustment of resistances to vary the constant, but that different scales should be used, each graduated to read directly, and the resistances altered automatically by the act of changing the scale. Such an arrangement was fitted up three years ago at the Acme Works, six scales being mounted on an hexagonal roller, the turning of which automatically inserted the proper resistance in series with the D'Arsonval galvanometer to make the corresponding scale read amperes or volts direct. Only one scale was visible at one time, so there was no possibility of mistake. Weakening of the magnets was compensated by a magnetic shunt provided with a fine adjustment. Speaking of the change of sensibility of D'Arsonval galvanometers with time he said that of the two instruments at the Central Institution above referred to, the original form had changed more than 3 per cent. in three years, whilst the modified form had remained perfectly constant since the alterations were made about two years ago. The change of sensibility he believed was due to the oxidation of the German silver suspension wires, whilst the other instrument, being suspended with phosphor bronze strip, had remained constant.

Captain SANKEY further described the resistance A used as an intermediary between the standard ohm and the rheostat B, and explained a diagram of it. He showed that there were two mercury contacts at the ends of each strip, and these were in parallel when the strips were in parallel. There were thus ten contacts in parallel at each end, and calling the resistance of each contact m and that of each strip s the resistance in parallel will be $s/5 + 2/10\ m$. When the strips are in series there are five mercury contacts in series, and the resistance is $5\ s + 5m$. The parallel is therefore one twenty-fifth of the series resistance, the mercury contacts being eliminated. Recent tests of the resistance A when in series gave 0·72678, and one twenty-fifth of this was 0·0290712. Direct measurement of the parallel resistance gave in two instances 0·029082 and 0·029075. He had tested a Siemens electro-dynamometer by the apparatus and found its constant to be 28·50. The instrument was then sent to the makers to be recalibrated, the new constant being 28·41. The original constant was 28·67, and hence his determination was equal to the mean of the two given by Messrs. Siemens Bros. Two errors in Table I. of the Paper were pointed out; in column 3 line 4 the number 0·417 should read 0·0104, and in column 4 line 3 the number 1·66 should be replaced by 1·57.

Prof. AYRTON exhibited several diagrams illustrating his previous

Digitized by Google

remarks, and showed several of the latest types of d'Arsonval galvanometers. He expressed his high admiration of the most perfect arrangements provided by Messrs. Willans and Robinson for testing the efficiencies of their steam engines, and he made some suggestions as to how their electrical test apparatus might be modified. The arrangement of platenoid sheet and d'Arsonval galvanometer used as a standard amperemeter at the Central Institution, and also the hexagonal multiple scale fitted up at the same works, were illustrated by diagrams, and the secular variations of sensibility of d'Arsonval were shown by means of tables. Referring to recent forms of instruments, he showed two new d'Arsonvals, both provided with adjustable magnetic shunts. One of these had been made by Mr. Pitkin, and the other by Messrs. Nalder Brothers and Co., the coil of the former instrument being wound with "manganin" wire, and that of the latter with platinoid. Both instruments had curved poles and freely suspended coils. Carpentier's long range d'Arsonval, an instrument deflecting through 180 degrees, was exhibited, together with a shunt, by means of which the sensibility would be greatly varied. Speaking of the shape which should be given to the coils of d'Arsonval galvanometers, he called attention to a note on the subject, presented to the Physical Society in March, 1890, by Mr. T. Mather, and he exhibited an instrument embodying the improvements there suggested. This galvanometer had a long narrow coil and no iron core, and for its winding was the most sensitive d'Arsonval he (Prof. Ayrton) had yet tested. On the subject of platinoid sheet rheostats, he said that instead of using a large surface 6ft. by 2ft. 2in., as Capt. Sankey and Mr. Andersen did, it would be better to have two sheets, one for currents, say, from 5 to 110 amperes, and the other from 50 to 1,100. If the narrow-coil low-resistance instrument mentioned above be used, the former platinoid sheet would require be be about 5in. square, and the latter 15in. square. With these the same range of current could be measured as with Capt. Sankey's large rheostat, and no temperature corrections whatever need be made to obtain an accuracy of one-fifth per cent. Further, the expenditure of power when measuring 1,100 amperes would only be 40 watts, whereas the strip described in the Paper absorbed about 1,300 watts when measuring the same current. The mercury contacts, although nominally eliminated, were nevertheless a source of uncertainty, and where the value of a resistance was of such vital importance their use should be avoided. Some of his students had recently tested such contacts and found them to vary greatly according to their condition, in one case the resistance fell from ·00266 to 0·00058, on being cleaned and reamalgamated.

Mr. CROMPTON said he wished to call attention to a few points which appeared to have been misunderstood. In the first place some persons said the Paper under discussion was unworthy of the Institution; with this he entirely disagreed, and thought the idea arose from misconception. He himself considered the Paper a capital one to commence the session with, and particularly interesting to rising electrical engineers. The details of practical testing apparatus were always valuable, and little dodges of great use to others always accompanied Papers such as the one before them. Again, English electrical engineers had established what was known as the English system of arranging central stations, viz., the combination of high-speed engines with direct driven-dynamos. Efficiency tests of this system showed that it gave better results than any other system. The Institution of Civil Engineers had acknowledged the completeness and accuracy of the "engine efficiency" tests of Messrs. Willans and Robinson; and he (Mr. Crompton) thought the electrical tests made as described in the Paper were quite accurate enough for present requirements. Speaking as one who had paid considerable attention to accurate electrical measurements, he doubted whether resistances could be measured to 1 part in 10,000, as stated in the draft Order in Council prepared by the Board of Trade. He had made many tests, and taken the greatest pains to obtain accuracy, but he found that it was not possible to get resistance boxes sufficiently well adjusted. Surface leakage difficulties were also very great, particularly in a London atmosphere. In their measurement at Chelmsford they preferred the zero method, and used d'Arsonval galvanometers, Clark's cells, and potentiometers. The chief reason for the preference was that it was so easy to repeat a measurement, and errors were so readily detected. He inquired why Prof. Ayrton had not used electromagnets instead of permanent ones in d'Arsonval galvanometers, in some such way as Mr. Kapp and himself had done in ammeters and voltmeters some years ago. At present he was engaged on an electromagnet instrument, which he hoped would be a great improvement on any yet made.

Mr. SWINBURNE described the system of measurement explained in the Paper as a calibrating system. In most station work it was usual to employ amperemeters and voltmeters, and he thought this would continue. Such instruments were, however, of two classes, the accuracies of which were very different. It would not be satisfactory to use a voltmeter intended for house work, and costing 3 or 4 guineas, in a station where an accuracy of a fraction of a per cent. was required. A letter balance was a very good thing for its purpose; but it would be totally unfit for chemical weighings. Captain Sankey and Mr. Andersen had, he understood, put up the arrangement described because they could not put confidence in other people's calibrations; neither could he himself, but a good instrument calibrated by the user would, he believed, be more satisfactory than the arrangement now before the meeting. He objected to "spot watching" in central stations, and thought the d'Arsonval galvanometer would not stay. A voltmeter might be accurately calibrated just as well as a d'Arsonval galvanometer. Most of the tests depended on standard cells, and considerable difference of opinion existed with regard to their reliability. If made in the same way from the same materials good agreement could be obtained between different cells, but this did not say they were right. Other persons were sceptical about the reliability of double-wound series resistances; and to examine this point his assistant, Mr. Bourne, made a coil of two insulated wires wound side by side. The insulation resistance was found to be over 600 megohms, and the insulation did not break down until the pressure between them amounted to 950 volts. This he considered proved that they were quite reliable. On the subject of platinoid he inquired whether its properties were permanent, and said that he could find no tungsten in it, and thought it was merely German silver with a large proportion of nickel. Speaking of resistance measurements he said that for small values the fall of potential method was the most suitable, and by it a single bar of an armature could be easily tested. With reference to the use of electromagnets mentioned by Mr. Crompton, he said that Mr. Boys had tried them, and found little or no advantage. Thomson galvanometers were much more sensitive than d'Arsonval's, and the only drawback was their being affected by external fields; but even this was not very important in null methods. In conclusion, he rather objected to a statement by Prof. Ayrton about the arrangement described by the authors being accurate enough for workshop purposes, and he pointed out that the most accurate measurements made, those of weight and length, were made in workshops; the former in commercial analysis, and the other by Whitworth measuring machines.

Mr. S. EVERSHED was surprised that more attention had not been paid to inaccuracies inherent in the instruments, for in addition to the variation of resistance with temperature, springs, torsion wires, magnets, &c., had temperature coefficients which ought to be investigated. Good magnets, with fairly closed circuits, were very permanent when left untouched; and he had used a tangent galvanometer with permanent magnet control for several years as a standard amperemeter, and the change had been very small. The magnets of one d'Arsonval galvanometer he tested had a temperature coefficient of about 0·01 per cent. This was considerably lower than those usually found for magnets used in magnetic observations (0·02 to 0·03 per cent.), but several samples of Jowitt's steel, tested by Mr. Vignoles, gave about 0·01 per cent. per °C. He therefore thought the ordinary coefficient was between 0·01 per cent. and 0·02 per cent. Speaking of the position of the point of attachment of the potential wires on the platinoid strips, he said they should be placed at some distance from the ends, so that the flow of current in the strip may be properly distributed. The new alloy "manganin" was, he believed, first tested in England by himself. The temperature coefficient, when received from the maker, was very small, and was negatived, but on having a wire drawn down to a smaller size its coefficient became positive. On inquiry he learned that to prevent this occurring a special method of drawing had to be adopted. Another specimen had a temperature coefficient about − 0·01 per cent. per °C. between 0deg. and about 160°C., but on keeping it heated to 160deg. its resistance fell considerably, and its specific resistance was permanently altered; its temperature coefficient was, however, about the same. From this he concluded that if permanency was required it should never be heated above 100°C. There was one form of d'Arsonval's galvanometer, which, although it had not been referred to, was worthy of attention, viz., the Weston voltmeter. He had recently tested one, and found it remarkably good and very accurate.

Mr. A. P. TROTTER wished to compliment the authors on the successful system they had carried out. He said it should be borne in mind that there were three classes of measurement carried out respectively in laboratories, workshops, and instrument-making factories. When the Society of Telegraph Engineers was first founded resistances were measured in miles of telegraph wire, and electromotive forces in Daniell cells; subsequently, when the name was changed to Society of Telegraph Engineers and Electricians, laboratory methods were employed; but now, as electrical engineers, it was necessary to measure in an engineering fashion. He considered the method adopted at Messrs. Willans and Robinson's a laboratory one, and thought the d'Arsonval galvanometer had not come to stay for workshop use, for "spot-watching" was not acceptable to engineers. Quartz fibres had revolutionised Thomson instruments, and they were highly sensitive and reliable. At present he did not see that workshop electrical measurements need be made to an accuracy of less than one in a thousand.

Mr. WILLANS said the need for such an arrangement as that fitted up by Captain Sankey and Mr. Andersen arose from the fact that dynamo makers had confidence in no measuring instruments except their own. They (Messrs. Willan and Robinson) formerly used Siemens' instruments, but the zero adjustment was troublesome, and only one person at a time could take the readings. With a spot of light two or more may take the reading, and this gave confidence to the parties interested. The average value of the quantities were those required, and Captain Sankey's method of taking the mean deflection, and then calibrating it, was, he thought, preferable to Mr. Crompton's zero method, or that of Prof. Ayrton, who relied on the spot always being in a definite place. The general result of the more accurate testing arrangements was to slightly lower the efficiencies. This, he said, was what might have been expected, for with imperfect instruments one was likely to take the highest of the several values obtained. Their experience was that most commercial instruments were unreliable when used in workshops near masses of iron, &c., hence the d'Arsonval form was adopted.

Captain SANKEY, in reply to Prof. Ayrton, said that the latter depended upon the accuracy of his scale, whilst they did not; hence the devices for obtaining proportionality were in their case unnecessary. By using a large rheostat they were able to employ a galvanometer of fairly high resistance with sufficient accuracy, and then their amperemeter galvanometer and their voltmeter galvanometer were interchangeable. The method of calibrating by using a known current was hardly possible in a workshop, for the copper deposit method was not convenient, and if another standard instrument be employed they would be depending on other people's calibrations. To avoid this, the method of checking and standardising described in the Paper was devised. To Mr. Evershed he pointed out that as the value of the mean deflection was determined immediately after every important test, the additional corrections he had referred to were eliminated. In designing the rheostats, they had taken care to put their potential wires at points where the flow was uniform.

Digitized by Google

Mr. ANDERSEN said that, in calibrating the mean deflection, only the standard ohm and the standard cell were relied on. Ohms could be made so as to be very near the Board of Trade requirement of 1 part in 10,000. As regards cells, Mr. Swinburne seemed to be under too much apprehension about them. He himself knew from experience that they could be made up to agree very closely with the standard value, when once one had got the "knack" of doing it. He was glad to know that "spot watching" had a good chance of being largely used by engineers, for a good spot was far superior to any pointer. Referring to the design of d'Arsonval galvanometers, he said some of the points mentioned by Prof. Ayrton were good, but he did not agree with the system of winding them with platinoid. An instrument so wound was necessarily about 25 times less sensitive than one wound with copper. Curved pole pieces and freely-suspended coils were good; the latter he himself had used several years ago. Magnetic shunts he thought unsuitable for workshop use. A resistance box was better, for one could trust a person to use the proper plugs. The six scales on the roller he considered unnecessary, for only one scale was required and five other sets of figures.

The CHAIRMAN (Mr. A. Siemens) agreed with Mr. Trotter as to the great advance made in electrical measurement since the formation of the society. The paper now before the Institution was a proof that electrical engineering had now become a science, and he doubted whether any other profession could show such a record of progress made in so short a time.

THE LIGHTING OF THE CITY.

The following report of the proceedings at Tuesday's meeting of the Commissioners of Sewers is from the *City Press* of Wednesday.

On the Court proceeding to consider the letter received from the City of London Electric Lighting Company asking for an extension of time of at least one year for carrying out the public lighting of the City,

The CLERK said he had received a further letter from the Company to the effect that there appeared to be some misapprehension with regard to the object of the application. In asking for an extension of time, the Company did not wish to relax their efforts, but the object was to ask the Commissioners to recognise the preliminaries for commencing the work, and to grant (if necessary) further time to complete the work. There was no intention of delaying the work; on the contrary, it would be pushed forward. The Company reminded the Commissioners that some time had been taken up in getting the consent of the Commissioners and the Board of Trade to the necessary transfers; but as the final designs for the lamps had been approved by the Commissioners the work of lighting other main thoroughfares would be at once proceeded with. The installation at the Mansion House would be ready by the 11th inst., and the work of opening the streets would be undertaken without delay.

Mr. SAYER moved that this communication, with the previous letter, should be referred to the Streets Committee.

Mr. PANNELL, in seconding this, said he did not think the Commissioners could enter into a discussion on these letters unless the whole Court was in possession of certain information which was possessed only by a few members of the Streets Committee.

Mr. TRELOAR described the application as preposterous, and said if it was granted the Commissioners would be the laughing stock of the community. He earnestly hoped there would be no more dilly-dallying.

Mr. Deputy EDMESTON hoped it would not go forth that that was the general opinion of the Commissioners; at least, it was not his opinion. He thought there was a great deal to be said as to why the Commissioners should not hurry this question, or place any block in the way of the Company's undertaking.

Mr. MORTON declared that the whole difficulty had arisen through the promotion of companies. The Commissioners were told distinctly on inquiry that the lighting companies which secured the contracts were able to carry out these works. They were assured that they were dealing with *bonâ fide* companies which could carry out the undertakings, but it seemed to him that the contracts had been used for the promotion of companies. There was the Pioneer Company, and then there was a final transfer to another company, and between these transfers an enormous amount of profit had been made by someone. He knew it was done with the consent of the Commissioners, and the Streets Committee had been fooled, and would be fooled again. But the Commissioners had a weapon against these companies, namely, the £3,000 on deposit, which could be distributed among the ratepayers to repay them for the disappointment in not having the electric light, and the Commissioners could go further by annulling the contracts which had been entered into, and send all speculators and adventurers about their business. He thought the citizens would ultimately have the advantage if these contracts were annulled.

Mr. Deputy ROSE-INNES said the application was a manifest injustice, because one Company had come in and knocked the other companies out in consequence of the low price the Company in question had offered to supply the light at. He could not but feel grossly dissatisfied at the application. Mr. Deputy Rose-Innes then referred to what had been done by the Commissioners in electric lighting, when some years ago a sum of between £900 and £1,000 was spent in experiments. With regard to what had been said by Mr. Morton, there was another security which the Commissioners possessed, namely, the large quantity of capital which had been invested in the streets, and if the present Company was a thoroughly good and solvent Company with a good banking credit, they ought not to hesitate in expending more capital by putting on more men, and making a struggle to complete the contracts.

Mr. C. T. HARRIS said he warned the Court against giving the contracts to the companies in the first instance, because they were not electric lighting companies. In his opinion it would be a fortunate thing if these contracts were annulled, and he moved as an amendment that the communications should be referred to a committee consisting of the whole Court.

Mr. SMALLMAN seconded this.

Mr. MCCARTHY thought if the Court decided not to grant the extension the work would be done, and the best thing to be done was to tell the Company plainly so.

Mr. CLOUDSLEY supported the amendment.

Mr. SLY considered the members would fail in their duty if they did not insist upon the Company carrying out the terms of their contract.

Mr. HUDSON failed to see how it was that the City of London would benefit by any extension of time, and at the proper stage of the debate he would be prepared to move that none be given.

Mr. STANLEY said he attended the Court that day on behalf of the General Purposes Committee, the Corporation having undertaken to light the Mansion House by electricity, and the committee was naturally alarmed at the proposed extension of time. The gas lamps at the Mansion House were being utilised for the reception of the electric light, and if it was postponed there would be neither gas nor electric light in the Mansion House. He therefore asked the Court to assist the General Purposes Committee in this matter, and to issue orders for the supply of the current to the Mansion House at least. He had been informed by the Secretary of the Company that the twelve months might not be needed, but that some extension would be necessary in order to complete their installation. He thought it was useless to talk about cancelling the contracts, because what would become of the plant? but he considered the best course to pursue was to send the matter to the Streets Committee, in order that they might find out how much work had been completed by the Company.

Mr. BRIDGMAN thought that there was something more in the application than appeared before the Court.

Mr. Deputy BEDFORD expressed a wish that some member of the Court would shed a little light on this complicated question by a brief clear statement of the position of affairs. Having spoken of the manner in which the subject had been complicated by the transfer of contracts from one company to another, the Deputy said this had been done at the expense of the ratepayers. Anyone looking at the state of the work in the streets knew that it would be impossible for the Company to complete their contract by February next; yet if the Commissioners were going to cancel these contracts the streets would be left in a terrible state in regard to future efforts of street lighting. He suggested that if the Company wanted two or three months' extension they should have it, but that penalties should be imposed if the time granted was exceeded.

Mr. GREENWOOD supported the amendment.

Mr. PANNELL contended that it was of little moment whether the question was settled by the Streets Committee or a committee of the whole Court. He concurred with the suggestion made by Mr. Deputy Bedford as to the granting of a small extension. As to the financial condition of the Company in question, he reminded the members of the Court that it possessed a million of money wherewith to carry out the work.

Mr. TRELOAR said it seemed to him that Mr. Pannell had been a little misleading with regard to the Pioneer Company—or he believed it was called a syndicate. The chairman of that syndicate was the late Lord Mayor, and the syndicate had financed or finessed the undertaking—and apparently they made some money out of it or someone did. Mr. Deputy Bedford has asked for someone to make a clear and lucid statement of the position of affairs; and if the late Lord Mayor had been present, he would have been able to supply the information, and put the matter properly and squarely before the members. He regretted that the late Lord Mayor had not attended the meeting that day for this purpose. As to the petition he did not think that the Court should give any extension, and that they should give a straightforward answer.

The CHAIRMAN then put the amendment, which he declared to be lost. A division was demanded, with the result that 34 voted in favour of the amendment and 28 against; majority six.

Mr. WALLACE then moved, as a further amendment, that the terms of the contract should be adhered to.

The amendment was put to the vote, and the CHAIRMAN declared it was carried unanimously.

THE ELECTRIC LIGHTING OF ST. PANCRAS.

At Tuesday's meeting of the London County Council the Finance Committee reported on the application from the Vestry of St. Pancras for sanction to borrow £60,000 for electric lighting works, to be repayable in 42 years. They had reported on the cost (£62,999) of the proposed works on November 17th, and recommended a loan of £56,300, repayable as to certain parts in varying periods of 5, 8, 15 and 30 years, such varying periods being fixed on the advice of the engineer, with reference to the probable life of the work on which the expenditure would be made. In consequence of the discussion which took place at the Council on November 17th they had seen a deputation from the Vestry, who had pointed out to them that the works as a whole would make up a permanent concern, and must, whenever necessary, be renewed from time to time out of the Vestry funds, so as to be kept always in good working order. They pointed out to the deputation that the Council was, under its present powers, precluded from granting loans for works for a longer period than 30 years, except for street improvements and bridges; but, while admitting this, they urged, in view of applications likely to be made by other parishes for loans to carry out similar works, that the Council should obtain statutory authority to grant loans spread over a period not exceeding 60 years. Under these circumstances the committee considered that it would be better for the Council to authorise the Vestry to borrow elsewhere than from the Council the sum of £60,000, leaving open the question of the Council's advancing this sum if Parliamentary authority was obtained for a longer period than 30 years. They recommended—(*a*) That the sanction of the Council be given under seal to the borrowing by the Vestry of St. Pancras of the sum of £60,000 towards defraying the cost of certain electric lighting works at a rate of interest not exceeding £4 per cent. per annum, and the principal being repaid by equal annual instalments within a period of 42 years from the date of the loan; (*b*) that the Council do apply to Parliament for power to make advances for electric lighting purposes to Vestries and other rating authorities within the county of London for periods not exceeding 60 years, and that it be referred to the Parliamentary Committee to take steps to obtain the necessary statutory authority for that purpose.

Mr. CAMPBELL said he would be the last to throw any obstruction in the way of so enterprising a parish as St. Pancras, but the duty of the Council with regard to these loans was to see that posterity was not unfairly burdened. The St. Pancras Vestry deserved the greatest credit for getting the Provisional Order to carry out their own electric lighting. He moved that the report be referred back to the committee for further consideration.

Mr. OSBORN supported Mr. Campbell's proposition. It seemed to him an extraordinary thing that they should take out of the rates sums of money to put up plant of very short life and spread their repayment over 42 years. Hitherto they had taken great care in granting money to local authorities to see that there was ample security for the money. In the case now before them they had none whatever. The parish of St. Pancras was starting with considerable doubt as to the success of the project, and they ought to remember the advances in electric lighting, which would involve alterations. In his opinion they ought not to go beyond 12 years, and certainly in no case ought they to go beyond 15.

Mr. CLARKE said he looked with alarm on the Council authorising loans for such a period on such perishable articles.

Mr. WESTACOTT reminded the Council that they were not agreeing to lend the St. Pancras Vestry the money; they were only authorising them to borrow it for a period not exceeding 42 years. He hoped the Council would encourage the Vestry of St. Pancras.

Lord LINGEN (the Chairman of the Finance Committee) said it was seldom that he appeared before the Council to advocate a long in preference to a short period of repayment. His own opinion was most strongly, as a rule, in favour of short periods. That doctrine had not always been readily welcomed there, and he hoped after the feeling which had been shown on that proposal the doctrine would receive more favour in future. They had told the applicants that with their present powers they could not lend to them for more than 30 years. It was impossible for the Council to shut its eyes to the fact that the example which St. Pancras set in that matter was an extremely important one. Parliament had expressed an opinion on the whole favourable—certainly not unfavourable—to the idea that the municipalities should undertake for themselves, and not leave to comparatively independent companies, such undertakings as involved the breaking up of the streets. That, on the whole, he thought was a sound policy. Supposing St. Pancras did not go into the open market to borrow this money, the only alternative was that they must go to Parliament, and he himself rather leaned to the idea that they should go to Parliament, because, if they considered the magnitude of London and the enormous importance of the lighting of it, as to its being done in the most efficient and economical manner, he thought it really was a question of Parliamentary magnitude. The Council, therefore, by adopting the recommendations of the Committee, did not commit themselves to any very dangerous precedent.

The amendment was rejected, and the recommendations of the Committee agreed to.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *November* 20, 1891.

The Berliner Microphone Patent.—The electrical sensation of the hour is the issue of the long-delayed Berliner microphone patent. It is the one to which the Bell Company has been looking for a long time as a possible means of extending its monopoly on the expiry of the Bell patent in 1893, and the original application for which was filed as early as June 4, 1877. That application covered in a broad way the microphone transmitter. At about the same time (July 20, 1877) Edison took the field with the same invention, and within a few months the pair were in interference in the Patent Office. Berliner's claim was transferred to the American Bell Telephone Company, and Edison's, originally assigned to the Western Union Telegraph Company, was transferred by that organisation to the Bell Company, under the famous agreement whereby the two were to have the monopoly respectively of the telegraph and telephone business. There were other subsidiary interferences besides the main one which dragged its slow course along year after year in the Patent Office. Meanwhile, both Berliner and Edison, in conflict on the broad claim, were industriously getting out detail patents, all of which became the property of the American Bell Telephone Company. These claims were filed during the latter part of 1877 and the early part of 1878. In 1880 the notorious Daniel Drawbaugh filed an application for a patent covering the same general idea. That application never got so far as an interference with either Edison or Berliner, but was made a shuttlecock between the Patent Office and the Drawbaugh attorneys for 11 years. The main question in the Drawbaugh case was whether the application should not be barred out altogether on the ground that the Edison carbon transmitter had been in public use two years before the Drawbaugh application in 1880. After a long period of cross-fire, proceedings to determine this question of public use were brought against Drawbaugh in the Patent Office; and Commissioner Simonds finally rejected, on this ground, the Drawbaugh application on October 28th last. In the meantime the Berliner-Edison interference had been finally settled in favour of Berliner in 1886, but the claims lay dormant until it became necessary for the continuance of the monopoly to drag them out. Even had the Bell Company desired to get the patent out it was not possible under Patent Office procedure so long as the Drawbaugh application, which might go into interference with it, was before the Office; that disposed of, the Berliner patent was issued bearing date November 17, 1891, No. 463,569.

The most important claim is as follows:—

> The method of producing in a circuit electrical undulations similar in form to sound waves, by causing the sound waves to vary the pressure between electrodes in constant contact, so as to strengthen and weaken the contact and thereby increase and diminish the resistance of the circuit substantially as described.

The following disclaimer is made:—

> I do not claim that I am the first inventor of the art of transmitting vocal and other sounds telegraphically by causing electrical undulations similar in form to the sound waves accompanying said sounds. Neither do I claim that I am the first who caused such electrical undulations by varying the resistance of an electric circuit in which a current was passing.

The claim, it will be seen, is broad and methodic, and although the apparatus shown and described in the application is in a very rudimentary form, the wording of the claim is such as might be construed by a liberal judge into covering the microphone transmitter pretty thoroughly. The foreign patents issued to Berliner are not of so broad a character, being confined in the main to details, and hence may not invalidate the present patent by their expiration. A strong fight will probably be made, however, in the Courts, before the Bell Telephone Company is allowed to continue its obnoxious

Digitized by Google

monopoly for another long term of years. The sentiment of the public and of the Courts will doubtless be against a broad interpretation of the Berliner claims, involving as it would 17 years of servitude to the Bell Telephone Company. The long delay of the claims in the Patent Office will influence their validity unfavourably, since it is only too evident that it was for the interest of the Bell Company to continue the interferences, both sides of which it owned, for the purpose of securing a patent of a later date. Of course the same reason is sufficient to account for the very slow progress of the Drawbaugh application, even supposing there was no collusion of any sort.

The immediate effect of the issue of the Berliner patent was a sharp rise in the stock of the Bell Telephone Company, which has been followed by a slight decline. The daily press is full of denunciations of the telephone monopoly, and there is every reason to believe that a most vigorous fight will be made if there is any attempt to enforce the Berliner patent.

SCANDINAVIAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

COPENHAGEN, *November* 28, 1891.

There is every likelihood of an electric railway being soon undertaken between Stockholm and Djursholm. A company holds a recent concession for an ordinary railway, and has now petitioned the Government that the concession may be so altered as to comprise electric traction. As soon as the necessary permission has been obtained the works will be commenced.

The Swedish State telephones have during October been used for 19,648 conversations on the interurban telephone lines, yielding receipts of 7,435kr., against a sum of 989kr. for the same month two years ago, and 1,962kr. for the same month last year, which affords a striking proof of the steady increase in the case of the telephone.

The Stockholm General Telephone Company does not see its way, it is understood, to avail itself of the permission to lay underground cables in the streets on the stipulated conditions, which the Company thinks would be ruinous. The Company has, therefore, in hand a plan involving the conversion of its entire system to a double-wire one with overhead cables.

It is on the whole marvellous how popular the telephone has become in Sweden, not only in the towns, but in poor and out-of-the-way country places. The Herjedale furnishes a striking example in this respect. In Sveg, a small place with only about 150 inhabitants, some 40 or 50 miles from the nearest railway station, the doctor, the chemist, the innkeeper, the tradesmen, and every farmer in the neighbourhood have telephonic connection, not only with the railway station but with two or three even more distant towns. They pay each 200kr., or £11, for the line ; 75kr. (£4. 3s.) for the telephone ; and 50kr. (£2. 15s.) fee for the first, and half that amount for subsequent years. There are tradesmen in the same district who have hardly more than 1,000kr. a year, and who have found it worth their while to invest in a telephone, the line of which has cost them 800kr., or nearly a whole year's income. It appears, too, that everybody finds it is well-spent money, and that they would not do without the telephone at any price.

The Budget for the Swedish State telegraphs during 1892 has recently been fixed. The calculated expenditure amounts to 1,325,000kr., which is a few thousand kroner more than the calculated expenditure for the current year.

A committee has been appointed in Sweden to look into and report upon questions bearing upon transmission of power by electricity, more especially as far as the prevention of accidents is concerned. The requisite regulations will be drawn up, and there can be no doubt that the transmission of power by electricity is coming to the fore in Sweden, where the many waterfalls furnish large quantities of power, which is at present barely utilised. Several large schemes are already under contemplation ; but I must reserve further mention of these for a future letter.

Projected Elevated Railway in Berlin.—The *Elektrotechnisches Echo* is informed that a settlement has been arrived at between the President of Police in Berlin, the Minister of Works, the Town Council, and Messrs. Siemens and Halske, with regard to building an elevated railway between the Zoological Gardens and the Warschauerstrasse.

CORRESPONDENCE.

PLATINOID *v.* COPPER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the discussion on Capt. Sankey's Paper at the Institution of Electrical Engineers, Prof. Ayrton raised an objection to the use of copper-wound d'Arsonval galvanometers for the purpose the authors used them, and said that a platinoid winding should always be used. The time being short, Capt. Sankey, in his reply, merely said that they preferred copper on account of its sensitiveness. Perhaps you will allow me to put the matter a little fuller in behalf of copper. Say you have one galvanometer P, wound with platinoid 100 turns, and R = 500. A similar galvanometer, C, wound with the same number of turns of copper of the same gauge, will be only 20ω ; the specific resistance of platinoid being approximately 25 times that of copper. It gives, therefore, for a given potential difference at its terminals, 25 times the deflection that P does ; which is extremely convenient when working low down.

At the same time, by adding in series with C a platinoid resistance of 480ω, you have a galvanometer which is absolutely identical with P, both in sensitiveness and resistance, and with a temperature coefficient only about $\frac{1}{480}$ per cent. higher. Surely a very low price to pay for having an instrument, when wanted for measuring small D · P's, twenty-five times as sensitive as the one all platinoid.

I have never had occasion to determine the temperature coefficient of platinoid in the slab, as used by Prof. Ayrton and at Thames Ditton, for current measurements, but should expect it to have a higher temperature coefficient than the comparatively small wire on a galvanometer, as platinoid wire shows a strong tendency to decrease in T.C. the finer it is drawn, so that the copper combination might be even better than the all platinoid one.—I am, &c.,

C. W. S. CRAWLEY.

THE TRUE FUNCTION OF THE THOMSON AIR-BLAST.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your editorial note upon the Van Depoele reciprocating drill (*The Electrician*, November 6th, p. 2) you say, "Our correspondent says nothing about the sparking which might reasonably be expected at the commutator of the dynamo. The Thomson-Houston Company are probably equal to the occasion with some such heroic device as an air-blast."

The misconception as to the purpose of the air-blast on the Thomson-Houston three-coil arc dynamo is widespread, due largely to the unfortunate statement in Prof. Thompson's invaluable and generally most accurate volume on "Dynamo Electric Machinery," Third Edition, 1888, p. 245.

For authority Prof. Elihu Thomson, the designer of the machine, may be quoted as follows: "I called Mr. Milton E. Thompson's attention in regard to the blowing out of the spark as expressing an erroneous idea in relation to the machine. This he would find expressed in Silvanus P. Thompson's 'Dynamo Electric Machinery,' that the air blast in the Thomson-Houston three-coil machine is for the purpose of blowing out the spark. This is not at all the case, and never was, and the air-blast was introduced for no other purpose than to make it possible to run the machine steadily at high differences of potential with a commutator which could be freely oiled. It was found in the early experience with the machine that it was possible to construct a machine up to 12 to 15 arc lamps which would retain the normal working condition without flashing over, as it is called—short circuiting across the slots and the short circuit being carried around. But beyond that potential difference there was an imminent danger of its occurring, although a 25-light machine might run for half an hour or an hour and a-half without any flashing or short circuiting over. Of course the tendency to flash over increased with the difference in potential. Now, it was also desirable to run the commutator with a film of oil,

Digitized by Google

to freely oil the machine; and when the commutator was freely oiled, the limiting potential which could exist without flashing over was much lower. Even a 10-light machine might flash readily if there was a good deal of oil on the commutator. In the early days men would oil the commutator. It was almost impossible to keep them from taking an oil-can and squirting on the commutator. . . . Another thing, the oil on the commutator, of course, diminished the wear; so that if there was any little roughening it was relieved a great deal from cutting and making copper dust around the commutator. . . . The reasoning used in getting the air-blast was this, that on the leaving of this segment there would be a small amount of current still fed from the segment to the brush, which would, as it were, tail off, and the sparks would be thicker at the brush and gradually thin out to a fine point and then stop. Then the segment would change polarity and go on to the other side. But, naturally, if the change of polarity was immediate on the cessation of that spark there might remain, as it were, from the spark, hot gas, which would enable the discharge to take place in the opposite direction, and that was a flash which would be carried over from the arc. My idea was simply to blow a cold blast of air, as it were, to drive that spark away and insert, no matter how thin, a layer of cold air before the reversal was accomplished, and in that way *to keep the insulation* of the machine. That process is found effective even with a three-coil commutator up to 3,500 or 4,000 volts, with the pressure, of course, slightly increased as we rise." (Discussion of Milton E. Thompson's "A Study of an Open Coil Arc Dynamo," A.I.E.E., May 21, 1891.)—I am, &c.,

J. Stanford Brown.

November 20, 1891.

HISTORICAL NOTE ON TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Remembering that cause and effect are equivalent, it occurred to me that the ordinary action of a Ruhmkorff coil machine might be reversed, so that, instead of producing a secondary current of high voltage and small quantity from a primary of low voltage and large quantity, we might produce a current of low voltage and large quantity from a current of high voltage and small quantity.

The simplest way to do this seemed to me to be by the use of two exactly similar Ruhmkorff coil machines. Connect the thick primary coil of the first machine with the battery, and the thin secondary coil with the thin secondary coil of the second machine. Then I supposed that we should get from the thick primary coil of the second a current similar to that in the primary coil of the first machine.

I do not clearly recollect whether I tried the experiment, but I brought the subject in this form before an eminent physicist, still living. His reply, dated December 31, 1866, was as follows:—"Cause and effect are certainly equivalent, but in your experiment you employ only one part of the effect of the primary. Try what is the effect of simply lifting the hammer of your first coil, not allowing it to fall. If your galvanometer be sensitive, you will get *some* effect."

This reply was beside the point, and simply told me what I knew before, namely, the mere fact of induction. What I wanted to know was whether we could reproduce our primary current in the way I have described.

If I rightly understand the subject, what I then suggested, about 25 years ago, is exactly what is done now by the modern transformer, which is simply a sort of modified induction apparatus with a primary and a secondary coil, by means of which a current of high voltage and small quantity can be changed into one of low voltage and large quantity, or *vice versâ*, as expressed by the formula $E\ C = E_1\ C_1$.

In an interesting Paper on the Frankfort Electrical Exhibition (*Nature*, 1st October, 1891), it is stated that Deprez and Carpentier's suggestion of alternate-current transformers was first put forward in 1881, and that the transformer of Gaulard and Gibbs appeared in 1883. Dr. Walmsley ("Electricity in the Service of Man," p. 684) writes to the effect that so widespread was the conviction that an induction coil would only work in the direction of raising electromotive force, that a patent to use this instrument, so as to increase the quantity of the induced current (as compared with that of the inducing current), was refused as impossible by the United States Office in 1883.—I am, &c.,

Cardiff: 47, Park-place, Chas. T. Whitmell.
November 26, 1891.

AN IMPORTANT POINT OF LAW.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: At meetings of local authorities the question is from time to time raised whether members interested in gas undertakings are entitled to vote or take part in discussions upon electric lighting matters. It may be useful, therefore, to the electrical industry to know what the law on this subject is. Mr. Sydney Morse has had occasion to take counsel's opinion upon the point; and, as I have obtained the permission of his clients to publish the opinion (which he has obtained from Mr. R. S., now Mr. Justice, Wright), I enclose it herewith, and trust that its publication by you may help to prevent the continuance of the injustice which is now frequently done to electrical companies by representatives of the gas interest.—I am, &c.,

E. Garcke.

Albert-buildings, Queen Victoria-street, E.C.,
December 2, 1891.

OPINION.

The Urban Sanitary Authority of ——— is the Corporation acting by the Council (*see* Sec. 6 of the Public Health Act, 1875), and consequently the present question turns on the construction of Sec. 22, Sub-sec. 3, of the Municipal Corporations Act, 1882. In my opinion, those members of the Council who are shareholders in the Gas Company have a direct pecuniary interest in the question whether or not the Council shall give their consent to the application by the Electric Light Company for a license under 45 and 46 Vict., c. 56, sec. 3, and such members are not entitled to vote on the question or to take part in the discussion of it. No penalty is attached to a breach of Sec. 22 Sub-sec. 3, and all that can be done in order to prevent such members from voting will be to get some member of the Council to draw the attention of the Mayor to the fact that the votes in question ought not to be received, and will be invalid. *See* Rule 10 of the 2nd Schedule to the Municipal Corporations Act, 1882.

(Signed) R. S. Wright.

45 and 46 Vic., ch. 50, sec. 22.

3. A member of the Council shall not vote or take part in the discussion of any matter before the Council or the Committee in which he has directly or indirectly, by himself or by his partners, any pecuniary interest.

THE THEORY OF THE WIMSHURST MACHINE.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In answer to Mr. Gray's letter, a proof of which you kindly sent me, I propose, in order not to protract to eternity this already long discussion, to go to the root of the matter and not to confine myself to mere questions of detail.

Prof. Thompson assumes that A_1 is positively electrified, and explains how this charge results in the negative electrification of the B sectors included in the quadrants I., and IV.; and he adds, "In the lower half of the machine similar actions are going on, with the result that the positive charges are brought to the left side of the machine by both discs, whilst negative charges are brought by both discs to the right side." This second part of the reactions is only possible if we allow either (i.) the primitive distribution supposed by Mr. Gray, or (ii.) the positive electrification of B_5 by the influence of A_1 across $\beta\beta_1$, the latter being to earth at the middle; this action is not possible. Prof. Thompson moreover declares that he does not bring in the diametrical conductors. There only remains the primitive electrification accepted by Mr. Gray, which is exactly what I said. Besides the objections urged by me in my last letter against this starting point, I will show you that it explains nothing. It is, in fact, quite as logical to allow that an analogous distribution exists on the second plate; there would, therefore, be no need to find a

Digitized by Google

theory for this curious machine because it would work by itself.

We must, I think, reject every hypothesis in which the original charge, that is to say, the auto-excitation, intervenes, so long as we do not know the exact source of it. Auto-excitation is not an essential part of the action of the machine, since the machine requires in certain cases to be excited. It is this more general case that we must consider.

Prof. Thompson does not explain the augmentation of the charges. As to Mr. Gray, I must recall his own words to his mind in order to show the great difference which exists between the theory he gave in his excellent book and that which he now gives. After having explained how the distribution is effected, Mr. Gray adds, "The two halves of B now in turn act as field-plates to induce charges on the carriers A of the disc A; and a little consideration will show that, *owing to the motion of this latter disc, the charges originally upon it will be increased by this action.*"

There is a wide difference between this theory and the one which I have given. As I remarked in *La Lumière Electrique* of October 10th, it follows from the passage underlined that at that time Mr. Gray admitted that the charges are accumulated on the carriers, fresh charges being added to the old ones as in ordinary multipliers, which is not possible because the same sector is in turn field plate and carrier, and in one complete revolution takes a positive charge, is put to earth, takes a negative charge, is again put to earth, takes a fresh positive charge.

Mr. Gray adds, "My theory was not intended to show how the final distribution arises from the primitive distribution." That is the very fault I complain of in the majority of theories put forth; the growth of the charges—we are in accord on that point now, Mr. Gray and I—being only the result of distribution effected; if we do not show how this distribution of electricity on the plates is caused, the action of the machine is not explained at all.

I have endeavoured, by studying the electrical reactions which are produced, to ascertain what is the *process* of this distribution; the theory which I gave, is it correct? It seemed so to me when I published it, though the objections which are raised against it would tend to make me doubt its accuracy. However, I would ask Mr. Gray to note the following:—

1. I not only claim the theory of the distribution as pointed out by me, but also the theory of the growth of the charges which, as I have already explained, I was the first to give.

2. It is no reason because one has not up to the present brought in the lateral inductive action of the carriers that it does not exist. By reason of the earthing of the sector under consideration there must be produced a sort of condenser action which gives a certain importance to this lateral induction; and feeble as it may be when compared with the action of the opposite sectors on the two plates, it is none the less sufficient to explain the excitation of a reciprocal action machine.

3. The action on sector A_7 pointed out by Mr. Gray cannot have the importance which he attributes to it. In fact, a careful study of my theory will show that I only bring in the lateral induction at the beginning, that is to say, when all the sectors are not as yet electrified; this lateral induction is, therefore, produced in the way I said. When all the sectors are electrified the symmetrical actions neutralize each other, and there only remain those of the opposite plates. Before the normal *régime* is established the lateral induction may, as Mr. Gray says, tend to diminish the action of the opposite carriers, but it is always much less than their action, and soon, owing to the multiplication of the charges, each sector will acquire its maximum charge and the normal *régime* will be established.

I thank you for having so hospitably opened your columns to me, and, as a justification of the length of this discussion, I can only point to the conclusions of my learned opponent.
—I am, &c.,
G. PELLISSIER.

Paris: November 26, 1891.

LEGAL INTELLIGENCE.

Savory and Moore v. London Electric Supply Corporation.

In the Chancery Division of the High Court of Justice, yesterday, the case of Savory and Moore *v.* London Electric Supply Corporation again came before Mr. Justice Kekewich. This was an action brought by the well-known firm of chemists in Bond-street, to restrain the defendants from carrying on their business in a manner likely to cause injury to the plaintiffs' premises. The case came before his Lordship a few months since, when it was adjourned in order that certain alterations should be effected by the defendants to prevent the possibility of any danger arising to the plaintiffs' premises.

Mr. HAMILTON, on behalf of the defendants, said he was not anxious that the case should come on before the whole of the alterations had been effected.

His LORDSHIP said he understood that the plaintiffs would be satisfied if an undertaking were given that no injury should be inflicted upon them by the defendants' works.

Mr. WARMINGTON, Q.C., for the plaintiffs, said that would hardly do. What the plaintiffs required was some kind of relief put into a distinct form, as they had a reasonable apprehension of injury.

Mr. HAMILTON, at the request of his Lordship, called Dr. Fleming and Major Waller, Manager of the defendants' Company, who gave evidence with the view of showing that since the case was before his Lordship a few months since, the defendants had taken steps to prevent any possible danger arising to the plaintiffs.

His LORDSHIP reserved his judgment until he had had an opportunity of reading over the evidence given on the last occasion.

Anglo-American Brush Electric Light Corporation v. King Brown and Co.

This appeal from the judgment of the First Division of the Court of Session, Edinburgh, revoking the Brush compound winding patent, came before the House of Lords yesterday. After hearing the Attorney-General on behalf of the appellants, the case was adjourned. Owing to the pressure on our space we are compelled to hold over our full report of the proceedings till next week.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

NOW READY.—"THE ELECTRICIAN" PRIMERS (38 in all. Vol. I., 20; Vol. II., 18), in two volumes. Price per volume 2s. paper covers, 2s. 6d. cloth; post free, 2s. 2d. and 2s. 9d. respectively. Single copies, 3d.; post free, 3½d. Prospectus on application to the Publisher.

TENDERS INVITED.—Our advertisement columns contain an announcement that the Town Council of Tiverton are prepared to receive offers from persons or companies for the transfer of the powers under the Provisional Orders obtained from the Board of Trade. Further information may be obtained from Mr. J. Siddalls, the borough engineer, Town Hall, Tiverton, and tenders must be sent in to Mr. C. Marshall Hole, town clerk, on or before January 1, 1892.

——— The Corporation of Worcester are desirous of receiving tenders with plans and specifications for constructing works for the supply of electricity to the central portion of the city. Tenders are to be delivered to Mr. Samuel Southall, the town clerk, at his office, Guildhall, Worcester, on or before February 14, 1892. Further particulars appear in our advertisement columns.

——— The Bournemouth Town Council invite tenders for lighting by electricity the pier, pleasure gardens and municipal buildings. Full particulars, forms of tender, and plans can be obtained of the borough engineer and surveyor, Mr. F. W. Lacey, and tenders are to be sent to the Town Clerk, Mr. J. Druitt, jun., by December 24th.

——— The North-Eastern Railway Company desire tenders for the supply, during the six months ended June 30, 1892, of telegraph apparatus and telegraph wire and line stores. Forms of tender may be obtained of Mr. Graves, Telegraph Department, York, and tenders must reach the Secretary, at York, by noon on Tuesday next, the 8th inst.

——— The Township of Galatz (Roumania) is desirous of granting a concession for the lighting of the town of Galatz by gas and electricity, and any person willing to undertake the business can see or procure at the Mayoralty the plan of the town and the terms and conditions. Tenders may be sent in up to January 20 (February 1), 1892, when the adjudication will take place.

CHRISTIANIA.—The contract for installing the central electric supply station has been given to Messrs. Schuckert and Co., of Nuremberg. The cost is estimated, according to a Reuter's telegram, at about £34,000.

Digitized by Google

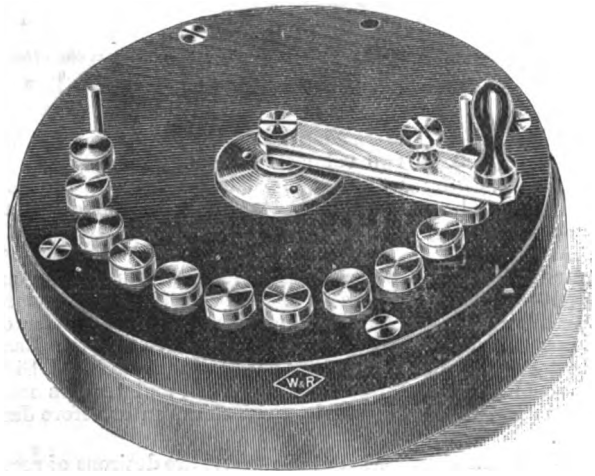
MESSRS. MOODY AND ANDREAE.—Mr. W. Andreae having withdrawn from his partnership in this firm, the name thereof has been changed to that of Moody Brothers. Messrs. Moody Brothers announce that they have taken over the stock and business premises of the late firm, and will execute all orders now in hand, and will continue to carry on the business as heretofore. Messrs. Moody Brothers are authorised to collect and give receipts for all money owing to the late firm, and they will also settle all the outstanding debts and liabilities.

——— We are informed by Mr. Walter Andreae that he is commencing business at 47A, Lower Belgrave-street, London, S.W., and will there carry on business, under the style of Walter Andreae and Co., as electrical engineers.

NEW FIRM.—We hear that Mr. Smeeton and Mr. Page, both of whom have been some years with the General Electric Company, have entered into partnership, trading as Messrs. Smeeton and Page, 63, Queen Victoria-street, E.C. Mr. Smeeton was pupil with Messrs. Goolden and Trotter, and since has been engineer to the General Electric Company on their foreign installations. Mr. Page was manager of the same firm's supply department.

BLYTH, NORTHUMBERLAND.—Messrs. Sanderson and Co. have recently taken over from Messrs. Nicholson and Jennings their contract for lighting the town of Blyth, Northumberland. We understand that Messrs. Sanderson and Co. have also established themselves as electrical engineers, &c., at High Quay.

MESSRS. HOWARD FARRAR AND CO.—The partnership between S. H. Farrar, G. Farrar, and J. P. Farrar, trading as above, has lapsed by effluxion of time. In future the Transvaal branch of the business will be carried on by S. H. and G. Farrar, and the colonial branches at Port Elizabeth and East London by J. P. Farrar. In both cases the present style of the firm will be retained. The London business has been transferred to Mr. F. A. Robinson, who has managed the same for some years, and will be carried on under the style of Messrs. F. A. Robinson and Co., Mr. Robinson acting as English agent for the Transvaal and Colonial houses. He will also liquidate the current business for Messrs. H. Farrar and Co., of London.



THE ELECTRICAL EXHIBITION AT ST. PETERSBURG.—In reference to our Note in a previous issue of *The Electrician*, the date of the opening of this Exhibition was given according to the Greek calendar, the date according to the Gregorian calendar would be the 25th December.

THE KRASNAPOLSKY WINTER GARDEN.—This elaborately decorated building has been lighted throughout by electricity, more than 1,500 incandescent lamps and 4 arc lamps being installed. The generating plant consists of three 80 H.P. engines driving three Crompton compound-wound dynamos, each capable of supplying 380 amperes at 110 volts. The installation has been carried out under the direction of Mr. G. E. Hartmans.

FYFE-MAIN ELECTRIC LIGHTING COMPANY.—This Company have successfully installed the electric light at the new premises of the *Field*, the *Queen*, and the *Law Times*, in Bream's-buildings, Chancery-lane, where two "Castle" dynamos generate the current for nine 15-ampere arc lamps in parallel, and more than a thousand incandescent lamps of 16, 32, 50, and 100 candle-power.

TEN-WAY SWITCHES.—Messrs. Woodhouse and Rawson United (Limited), of 88, Queen Victoria-street, E.C., are stocking switches of the type shown in the illustration. These may be had either 12 or 20-way, and are mounted on slate bases, neatly fitted into wooden frames. They are carefully designed, and no doubt will be much in demand.

S. Z. DE FERRANTI (LIMITED).—The *employés* of this firm held their annual dinner at the Wool Exchange Restaurant, Coleman-street, on Saturday evening last, when an exceptionally pleasant evening was spent by the men and their guests. Mr. Kilgour, the foreman, was in the chair, and was supported by Mr. Pascoe. After the usual loyal toasts, the Chairman proposed the health of the firm, and Mr. Ferranti, in replying, referred to the position which the electrical industry had now attained, and the fact of their having been so actively engaged at the inception of it should give them something to look back upon in years to come with considerable pleasure. The electric light particularly had passed through serious difficulties, both legislative as well as financial, but now that it had got free of this he predicted an extension upon which it was hardly possible to speculate at present.

ELECTRICAL TANNING.—A pamphlet containing a considerable number of experts' reports on the Groth process, a reprint of the Paper read before the Society of Chemical Industry, and a report of the trial of the British Tanning Company *v.* Groth, has been issued by Mr. L. A. Groth, of 3, Tokenhouse-buildings.

WOODHOUSE AND RAWSON UNITED (LIMITED).—This firm are issuing Section 8 of their catalogue. This section deals with electrical machinery and apparatus connected therewith, and contains illustrated particulars and prices of electric cranes (fixed and portable), capstans, winches, hoists, drills, ore separators, tools, lathes, drilling machines, welders, &c.

C. AND C. MOTOR PATENTS.—Messrs. Shippey Bros. write that it is announced in the trade that the Pilson Electric Company have secured an exclusive licence to manufacture and supply the Curtis, Crocker, and Wheeler electric motors and pumps for England and France. These motors are sold in Europe under the various trade marks of the C. and C., C. and W., and Standard systems.

MESSRS. J. E. H. GORDON AND COMPANY (LIMITED).—We learn that this firm will have completed their Larne installation shortly, and that the Bray installation is making very satisfactory progress; the latter installation is somewhat similar to that at Carlow, water-power being used with auxiliary steam. The actual number of lights at Larne is 4,000, with an ultimate 8,000; at Bray 10,000, with an ultimate 20,000.

ALTERION COMPANY (LIMITED).—A resolution was passed at a meeting held on November 10th that this Company, carrying on business as electrical engineers, at 20, Mount Stuart-square, Bute Docks, Cardiff, be voluntarily wound up, and that Mr. John Tellefsen be liquidator.

NEW COMPANIES, STATUTORY RETURNS, &c.

CONNELLY MOTOR COMPANY (LIMITED).—This Company was registered on November 23, 1891, with a capital of £70,000, in £1 shares, by Wynne, Holme, and Wynne, 40, Chancery-lane, W.C. The objects are to purchase or acquire, and to work, use, or sell any patents, and licences under patents, and any other property whatever, including therein any tramways and statutory or other powers to make tramways, and the business of any company, firm, or person relating to the construction, equipment, or working of tramways, or the manufacture of gas, oil, or other motors and machinery for use on tramways.

FREEMAN'S (LIMITED).—Registered by Bonner, Wright, Thompson, and Co., Ingram House, 165, Fenchurch-street, E.C., with a capital of £50,000, in £10 shares. Objects: To carry on, in all their respective branches, the businesses of builders and contractors, the general business of an electric light, heat and power supply company, &c.

RICHARD HILL AND CO. (LIMITED).—This Company was registered on November 26, 1891, with a capital of £50,000, in £10 shares, by Waterlow and Sons (Limited), London-wall, E.C. The objects are to acquire and carry on the business of iron and steel manufacturers, steel converters, general engineers, machinists, rollers of iron and steel for wire rods, bars, hoops, rivets, or plates, smiths, fitters, &c., carried on by Richard Hill at the Newport Rolling Mills and the Marsh Wire Works, at Middlesbrough, Yorkshire, under the style of "Richard Hill and Co." Registered office: Middlesbrough, Yorkshire.

KITTO CYCLE COMPANY (LIMITED).—This Company was registered on the 24th ult., with a capital of £20,000, in £1 shares, by Sir Joseph Causton and Sons, 9, Eastcheap, E.C. The objects are to carry on the business of manufacturers of cycles generally, and to carry on the business of electrical engineers and manufacturers of and dealers in machinery and apparatus relating to the production of electric force and power; to generate, accumulate, distribute, and supply electricity; and to construct and lay down all necessary cables, wires, lines, accumulators, lamps, and works. The first Directors are J. Willoughby, G. F. Youlton, W. H. Jennings, and W. H. Kitto (Managing Director), all of Plymouth. Registered office: 197, Union-street, Plymouth.

E. M. MALLETT AND CO. (LIMITED).—This Company was registered on November 24, 1891, with a capital of £12,000, in £1 shares, by E. M. Mallett, 1, Gresham-buildings, E.C. The objects are to enter into an agreement with E. M. Mallett and Co. for the acquisition of certain contracts, and to carry on the business of mechanical engineers, smelters, founders, workers in metal and clay, &c. There will be no Board of Directors, but for seven years the Company will be conducted by E. M. Mallett and J. Luttman, Managing Directors.

MILLER AND CO. (LIMITED).—This Company has been registered in Scotland, with a capital of £100,000, in £5 shares, to acquire and carry on the business of Miller and Co., engineers and ironfounders, Vulcan Foundry, Coatbridge.

Digitized by Google

NATIONAL TELEGRAPH WORKS COMPANY (LIMITED).—This Company was registered on November 27, 1891, with a capital of £5,000, divided into 990 ordinary shares of £5 each and 50 founders' shares of £1 each, by A. P. Honeyman, 9 Bennett's Hill, Birmingham. The objects are to enter into an agreement with Joseph S. Lewis to carry on the business of manufacturers, or merchants of, or contractors for, pressed-steel, iron, or other metal; to carry on business as electrical engineers and contractors, and manufacturers of electrical appliances, insulated wires, cables, insulating materials, and other apparatus, materials and things required for or capable of being used in connection with electricity or other similar work; and to supply, equip, maintain, work, hire, let, sell, and deal in all apparatus and materials used in connection with electrical engineering. The number of Directors is not to be less than two nor more than six, the first being J. S. Lewis, of The Swifts, Yardley, near Birmingham (telegraph engineer), and A. H. Church, 242, Frederick-road, Aston Park, near Birmingham (electrical engineer). Qualification, 50 ordinary or 1 founders' share. Remuneration as fixed at the general meeting.

PATENT ELECTRO-MAGNETIC SYNDICATE (LIMITED).—This Company was registered on November 26, 1891, with a capital of £25,000, in £1 shares, by W. Beck, 2, East India-avenue, E.C. The objects are to acquire the interest in the invention relating to improvements in electrical appliances, for which W. R. May, of St. Paul's-road, Canonbury, has obtained provisional protection, and which is numbered 12,150 of 1891, together with all the patents, privileges, or advantages, now held or to be acquired by him; to adopt certain agreements for the above purpose; and to carry on the manufacture and sale of electrical or magnetic movements or timepieces generally; and the business of engineers, machinists, merchants, and dealers.

WM. ROBINSON AND CO. (LIMITED).—This Company was registered on November 28, 1891, with a capital of £5,000, in £10 shares, by Jordan and Sons, 120, Chancery-lane, W.C. The objects are to acquire the business carried on by A. H. Kreuser, at Wolverhampton; and to carry on the business (amongst others) of founders, wire drawers, tube makers, galvanisers, electro-platers, &c.

W. G. SKELTON, CORBITT, AND CO. (LIMITED).—This Company was registered on November 24, 1891, with a capital of £20,000, in £10 shares, by Pilgrim and Phillips, 17, Coleman-street, E.C. The objects are to acquire and carry on the businesses of iron and brass founders, steel makers, &c., by W. G. Skelton and Co., at Sheffield, and by William Corbitt and Co. (Limited), at Rotherham, Yorks. Registered office: Sheffield Grate Works, Rotherham, Yorks.

WADDLE FOUNDRY COMPANY (LIMITED).—This Company was registered on November 26, 1891, with a capital of £5,000, in £50 shares, to acquire and work the Penrhos Foundry, Llanelly, Carnarvon, carried on by M. R. Waddle; and to carry on the business of mechanical engineers, machine, and engineering tool makers, boiler makers, iron and brass founders, chemical manufacturers, &c. Registered by Andrew Wood and Co., 8, Great James-street, Bedford-row, W.C.

HENRY WALKER AND SON (LIMITED).—This Company was registered on November 28, 1891, with a capital of £50,000, in £5 shares, by T. W. Rossiter, 7, Ely-place, E.C. The objects are to acquire and carry on the business of ironfounders and ironmongers, carried on by H. Walker and J. G. Walker, at Gallowgate Ironworks, and 55, Westgate-road, Newcastle-upon-Tyne; and to carry on the business of heating, ventilating, manufacturing, electrical, and general engineers, plumbers, gasfitters, iron and brass founders, &c.

WINTERBOTTOM BOOK CLOTH COMPANY (LIMITED).—The objects of this Company, registered with a capital of £800,000, include the carrying on of the business of electrical and mechanical engineers.

CROMPTON AND CO. (LIMITED).—The following was filed on November 17, 1891:—At an extraordinary general meeting of the members of Crompton and Co. (Limited), duly convened and holden at the registered offices of the Company, Mansion House-buildings, in the City of London, on Tuesday, November 3, 1891, the following resolution was unanimously passed. [See *The Electrician*, Nov. 6, p. 20.] The usual forms for such increase were also filed on November 17, 1891. The above Company was registered on July 30, 1888, with a capital of £140,000, divided into 20,000 7 per cent. preference and 8,000 ordinary shares of £5 each. At the time of the statutory return, December 19, 1888, 15,576 preference shares had been taken up, and upon these £59,029. 10s. (including £3,629. 10s. payments in full) had been paid, leaving £2,988. 10s. unpaid. At the date of the last return all the shares had been taken up, the full amounts called on the preference, and, with the exception of £20, paid. The ordinary shares were issued to J. F. Allright (2,432) and R. E. B. Crompton (5,563) as fully paid. Office: Mansion House-buildings, E.C.

ELECTRICAL INVENTIONS COMPANY (LIMITED).—The above-named Company was registered on September 18, 1891, with a capital of £35,000, in £1 shares, filed on November 28, 1891. Its first registered office is situated at 57, Moorgate-street, London, E.C.

EUROPEAN SIMS-EDISON ELECTRICAL TORPEDO COMPANY (LIMITED).—An agreement made July 3, 1891 (and filed on November 25, 1891), between the Sims-Edison Electrical Torpedo Company (called the Sims-Edison Company), incorporated under the laws of the State of New York, of the first part, and the above Company of the second part, states that, whereas the former Company is the exclusive owner of certain inventions and improvements in electrical torpedoes, for which patents have been granted in England, France, Belgium, Luxembourg, Austria, and Italy, and whereas the Government of the United States of America have purchased eleven of the said electrical torpedoes for $125,000, and have ordered more; and whereas the Sims-Edison Company is desirous of disposing of all its rights to the said invention obtained or obtainable in Europe, India, Burmah, and the British Colonies; and since the European Company has been registered with a share capital of £210,000, divided into 10,000 £20 and 1,000 £1 shares; it is therefore agreed that the Sims-Edison Company shall sell and convey to the European Company the letters patent granted in England, Nos. 2,614 of 1883 and 439 of 1891; France, Nos. 169,446 of 1885 and 210,941 of 1891; Belgium, No. 69,212 of 1885 and one pending for 1891 Austria, No. 21,671 of 1885 and one pending for 1891; Luxembourg, dated June 11, 1885, and No. 1,401 of January 22, 1891; and Italy, No. 83, volume 57, of January 22, 1891; and all letters patent which may be obtained; and in full consideration the sum of £175,000, payable £18,000 in cash, and the remainder in fully-paid-up ordinary shares in the purchasing Company, to be allotted to the vendors or their nominees.

A supplementary agreement of July 28, 1891 (and filed on November 25th) fixed the purchase consideration as follows:—£18,000 in cash, as heretofore, £66,660 by the allotment of 3,333 fully-paid ordinary shares, to be numbered 8 to 3,340 inclusive, and the remainder in cash or fully-paid shares, at the option of the European Company.

An agreement, made August 17, 1891 (filed on November 25, 1891) supplemental to the above, states that whereas £800 in cash had been paid to the Sims-Edison Company, as part payment of the £175,000, and it had been proposed to pay a further sum of £2,200, it was agreed that within seven days from the date of the agreement the £2,200 should be paid to the vendor Company, and that the latter Company should hand over the patterns, moulds, and designs necessary for the commencement of the manufacture of the electrical torpedoes, and that Mr. W. Scott Sims should forthwith proceed to England to superintend the work.

An agreement dated August 24, 1891 (filed also on November 25th), determines that since the Sims-Edison Company are desirous that the manufacture of lifeboats under the above patents, in England, should be commenced, and that orders should be given by the European Company for the construction of a lifeboat combining the principle of the patents, the European Company, therefore, shall give orders for the construction of such a lifeboat, under the superintendence of Mr. W. Scott Sims, or another engineer of the Company, and that in consideration of the said undertaking the purchase price shall be reduced by £25,000.

An agreement made November 26, 1891 (and filed on the 28th following) states that since £3,000 in cash has been paid and 3,333 fully-paid ordinary shares have been allotted to the vendor Company, acting under the power given them, the European Company determine that the remainder of the reduced purchase consideration shall be fully satisfied by the allotment of 4,017 fully-paid ordinary shares to the vendor Company, these shares to be numbered 3,341 to 7,357 inclusive.

GLOBE ELECTRIC COMPANY (LIMITED).—The first registered office of the above-named Company, which was registered on November 4, 1891 with a capital of £10,000, in £1 shares, is situated at 36, Great James-street, Bedford-row, London, W.C. (Filed on November 28, 1891.)

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—Our advertisement columns announce that the Directors of this Company have declared an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum, free of income tax, for the quarter ended September 30th last, and payable on the 21st inst. The books of the Company will be closed from the 14th to the 19th inst., both days inclusive.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts of this Company for the week ended November 29th amounted to £806; aggregate receipts for half-year to date, £15,943.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of November were £3,200, as compared with £3,193 in the corresponding month of last year.

DAN RYLANDS (LIMITED).—This Company, well known as the makers of glass-lined tubing for electrical purposes, have just placed on the market a further issue of 16,000 cumulative preference shares of £5 each, at a premium of £1 per share, and 6,000 ordinary shares of £5 each, at a premium of £5 per share.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company announce the payment on January 14th next of interest of 3s. per share, less income tax, being at the rate of 6 per cent. per annum on the preference shares of the Company, for the quarter ending December 31st; and the usual interim dividend of 2s. 6d. per share on the ordinary shares, free of income tax, in respect of profits for the quarter ended September 30th. The transfer books of the Company will be closed from January 7th to 14th, both days inclusive. The traffic receipts of this Company for the month of November, 1891, amounted to £60,053, against £58,975 in the corresponding period of 1890, being an increase of £1,078.

EASTERN EXTENSION TELEGRAPH COMPANY (LIMITED).—The receipts of this Company for November amounted to £40,686, as against £44,742 in the corresponding period of last year, showing a decrease of £4,056.

ELECTRIC INSTALLATION AND MAINTENANCE COMPANY (LIMITED).—An extraordinary general meeting of this Company was held yesterday (Thursday) at the registered offices, 4, Great Winchester-street, London, E.C., when the subjoined resolutions were proposed:—1. That the name of the Company be changed from the "Electric Installation and Maintenance Company (Limited)" to the "Crystal Palace District Electric Supply Company (Limited)." 2. That each of the existing £10 shares be divided into ten £1 shares. 3. That the existing Articles of Association of the Company be cancelled, and that the fresh articles (which can be inspected at the Company's offices, or at the offices of the solicitors, Messrs. Pyke and Voules, 85, Gracechurch-street, E.C.) be substituted therefor. The resolutions were passed unanimously, and will be sub-

Digitized by Google

mitted for confirmation as special resolutions to a second extraordinary meeting, to be held on Saturday, the 19th inst. The following resolution was also passed, and will not require confirmation:—That the remuneration of the Directors for their services up to December 25th next be fixed in accordance with Article 83.

HALIFAX AND BERMUDAS CABLE COMPANY (LIMITED).—*The Statist* of November 28th contains an article calling attention to the position of this Company, with special reference to a prospectus which is being issued by a firm of circular addressers, &c., offering small parcels of the Company's Four and a-Half per Cent. Bonds, at £106 for each £100 debenture. *The Statist* particularly takes exception to the manner in which these bonds are offered to the public, and to some of the statements made in the prospectus. There is no indication that the prospectus is issued by the authority of the Company.

SHIPPEY BROTHERS (LIMITED).—We are informed that the bulk of the shares recently placed on the market in this Company have been purchased by Messrs. Gwynne and Co., Engineers, of Essex-street Works, Strand.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the half-month to November 30th were £2,333 as compared with £2,865 in the corresponding period of last year showing a decrease of £532.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 708.—Vol. XXVIII. FRIDAY, DECEMBER 11, 1891. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6.

NOTES.

One of the most useful and certainly most disinterested efforts of the London County Council has been their action in demanding a better standard of light than the "Parliamentary candle." One of the highest authorities on this subject, as well as on the complicated art of gas testing, which is generally called photometry, is Mr. W. J. Dibdin, the chemist to the Council. The credit of this movement is probably due to him; and although the matter seems to be essentially one which should have been taken up by the Standards Department of the Board of Trade, the joint action of this body with the London County Council, financed in a truly British fashion by the public spirit of the South Metropolitan Gas Company, will no doubt lead to a practical issue. The effort is to obtain a more exact standard, not necessarily a new one. The candle is a unit of very convenient magnitude, and it is to be hoped that the construction of the new standard will be confined to reproducing the mean value of the old candle.

A very just complaint was made by a correspondent to the *Financial News* on the 7th inst., that he had been canvassed by a firm of contractors who solicited the wiring of his house, they representing themselves to be the engineers of the local supply company. Their tender was accepted on the assurance that current would be supplied at once; but with the ingenious and thoughtful stipulation that the cost of wiring would not be paid for until the current was supplied. Like many others, the owner of the house has been daily reminded of the blessings of electric light by empty lamp-holders, if not dangling wires; and for a twelvemonth, while the newly decorated house has been soiled by gas, he has waited for electric current, and the contractors, probably with equal impatience, have waited for current coin. On applying to the supply company he learns that they will put down the necessary mains for £350, and they generously offer to expend this sum for this purpose if he will take 35 shares at £10 each. The Company, having repudiated the authority of the contractors to make promises as to the date when the current would be supplied, is giving the matter further consideration. Such promises, or at all events assurances, are not uncommon, and the precaution adopted in this case will probably deter imaginative contractors from making rash guarantees.

In giving his judgment in an action brought by an Edinburgh electrotyper against a Newcastle firm of dynamo maker, Lord Kyllachy, as will be seen in our Legal Intelligence columns, arrived by a process of elimination face to face with a somewhat unpleasant alternative. The dynamo in dispute was supplied in September last year, proved unsatisfactory, and was ultimately returned. The plaintiff said the machine was at fault; the defendants blamed the bath and the general arrangements, and disclaimed all idea of having contracted to furnish a dynamo for the particular purpose of electrotyping. According to Lord Kyllachy, neither side proved its case in Court. The dynamo had, however, been fetched back from Newcastle, where it had lain several months, and had been tested with highly satisfactory results. This fact, said the Judge, left him no alternative but to "assoilzie" the defendants or to infer fraud on their part; and there being no evidence whatever in support of such a charge, he naturally preferred to sit on the more comfortable horn of the dilemma which he had conjured up.

An important addition to our knowledge of phosphorence has been recently made by M. Henri Becquerel, and a brief account of his experiments will be found in the *Comptes Rendus* for November. The elder Becquerel, the inventor of the phosphoroscope, found that the light given off by a phosphorescent body diminished according to an exponential law of the time. The law, however, was merely approximate, and was only supposed to apply for short intervals of time. By studying the behaviour of bodies which remain shining for several minutes after the removal of the incident light, M. H. Becquerel has succeeded in finding a law which represents, with considerable accuracy, the manner in which the light fades away. In order to account theoretically for his results, he supposes that the molecular vibrations, to which the phosphorescence is due, are resisted by the medium in which they occur in much the same way as the oscillations of a galvanometer needle are gradually decreased owing to the resistance of the surrounding air. He assumes that the resisting force is proportional to the square of the velocity, and finds that the intensity of the phosphorescent light is represented by the reciprocal of $(a + b\,t^2)$, where a and b are constants, and t is the time reckoned from the removal of the incident light. This law is apparently closely fulfilled if the phosphorescent substance only gives out one kind of light. When a mixture of lights is emitted by the substance, the law in its simple form no longer holds, for it is found that the

Digitized by Google

values of a and b vary with the colour of the light. Thus when a substance emits two kinds of light, the expression for the intensity of the glow consists of two terms, each of the same form, but with different values for the constants a and b. These facts have been verified by experiments on calcium and other salts, the luminosity of which persists for more than half an hour after the removal of the light. The agreement of the experimental measurement with the numbers deduced from the formula is very close; yet, as there are as many as four constants at disposal, the results are not more concordant than one would be led to expect. M. BECQUEREL'S theory would have been more thoroughly proved if the light had been examined through coloured glasses, so as to separately investigate the light corresponding with the different terms in the formula.

AFTER giving a brief sketch of the very meagre state of knowledge of the heating of conductors by electric currents, we observed last week that nothing of importance had been done since 1889 until the recent reading of a Paper before the Royal Society on the subject; and whatever criticisms may have been offered, there can be no question that the Paper was, as we remarked, of importance. Criticism of scientific work differs widely from that of the drama, art, or literature, because, whether made at a discussion after the reading of a Paper, or in the columns of a technical paper, every facility is open to the author for explanation or, if need be, of refutation. The abstract of this Paper was not full enough to justify further criticism, and our comments were chiefly aimed at elucidating various points which were not sufficiently described. Such elucidation can come only from the authors; but only a few additional details have reached us, and these have come by a very roundabout channel. The dimensions of the water-jacket cylinder were, we hear, 32·5 centimetres long, by 7·62 centimetres external, and 5·8 centimetres internal diameter; it was of course placed horizontally. The experiments were made with the view of ascertaining the behaviour of wires in Cardew voltmeters. The curves which we had constructed were not the same as those accompanying the Paper, and the peculiar disturbances we observed in them were due, it is suggested, to irregularities in the composition of the wires or errors in measuring their diameter. The investigation of the heating of very thin wires is of course new; our sketch showed that little was known about it except that the ordinary law was not followed; and it is possible that the complete Paper, which we understand represents a very large amount of work, may contain information of a more generally applicable character than the abstract foreshadowed.

Nottingham.—The Town Council has empowered a special committee to spend £25,000 to £30,000 in lighting a central section of the borough by electricity.

St. Ives (Hunts).—At the last meeting of the Town Council the desirability of adopting the electric light was referred to a special committee for investigation and report.

Plymouth.—The Board of Trade give notice that they have revoked the Plymouth Electric Lighting Order, 1890, and that the revocation is to take effect from November 24th.

Royal Society.—The following Paper was down for reading yesterday before the Royal Society:—"Repulsion and Rotation produced by Alternating Electric Currents," by G. T. Walker.

Zonal Spherical Harmonics.—The December number of the *Philosophical Magazine* contains Prof. J. Perry's Table of Zonal Spherical Harmonics, together with several worked-out examples.

Lambeth Vestry.—The House-to-House Electric Company offered to transfer its Order to the Vestry at a price equivalent to the estimated cost of obtaining a new Order by the Vestry. The offer has been declined.

Richmond (Surrey).—At a meeting of the Town Council held on Tuesday, it was decided by a large majority to seal a contract with Messrs. Latimer Clark, Muirhead and Co., for the electric lighting of Richmond, for a period of 30 years.

Glasgow.—At the meeting of the Town Council last week it was decided, by 56 votes to 7, to go on with the low-pressure scheme of electrical distribution, and to employ the services of Prof. A. B. W. Kennedy as consulting engineer.

Telephone Licences.—The Secretary to the Post Office has intimated to Mr. A. Erskine Muirhead, Managing Director of the Caledonian Telephone Company, that the Government will now receive their application for a licence for exchange business.

Telephony in Greece.—A telephonic service will be established next spring between Athens and the Piræus, and the necessary apparatus has already been ordered. The yearly subscription will be 200f. in Athens and 175f. in the Piræus.

Bilbao.—*Industries* reports that a successful trial has been made with an electric tramway at Bilbao. The work of transformation from a horse line to an electric line has been going on for more than two years. The current will be supplied by overhead conductors.

Old Students' Association.—A most successful smoking concert was held on Friday last at Masons' Hall Tavern. A very first-rate programme was provided, and there was a large attendance of members and friends. The hon. secretary announced the names of no less than 27 new members and associates.

Overhead Telephone Wires in Sheffield.—The Chief Constable reports that an accident has occurred to a fire escape on account of insufficient headway between certain overhead telephone wires and the surface of the street; and the borough surveyor has been instructed to write to the two telephone companies, requesting them to have all overhead wires crossing public streets altered so as to leave a clear headway of 35 feet.

Electricity in the City.—At the meeting of the Common Council last week it was stated that the present electric light standards were not approved of, and were going to be removed. It was also stated that the electric lighting of the Mansion House was progressing satisfactorily, and the light would be tested this week. If the lighting of the City streets was postponed it would not affect the Mansion House, because it would be lighted by a special wire.

A Damaged Cable.—The cable off Lowestoft, known as the Northernmost Cable, the property of Reuter's Agency, has been severed, presumably by a vessel dragging at her anchor during the fog on Monday night. The cable, which communicated with Germany, was laid in 1866, and it has been ascertained that the damage sustained is about ten miles east from the Corton Light. The work of repairing the cable will be at once proceeded with by the s.s. "Monarch."

Electric Launches for the Seaside.—Mr. W. S. Sargeant, of Chiswick, has been successful in gaining the £25 prize as offered by the Paignton Promenade Pier and Torquay Ferry Company, for the best designs and drawing for electric launches plying between Paignton and Torquay; also for a 65ft. steam launch to carry 100 passengers for the proposed trip round Torbay. The vessels are to be built in the best possible manner and to the Board of Trade's requirements, and to be delivered at Torquay on May 1, 1892.

Digitized by Google

Hull.—At the last meeting of the Electric Lighting Committee of the Council the minutes of the Sub-Committee, containing the electrical engineer's recommendations and report, were confirmed. The plant required is to be capable of supplying 8,500 8 c.p. lights in the first instance. Siemens' shunt-wound dynamos, running at 115 and 150 volts (the latter for charging accumulators if necessary), are recommended, the former being 115 unit, and the latter 45 unit machines. A modification of the Crompton system of mains is proposed.

The Theatrophone in London.—A preliminary trial of several theatrophones was made at the Savoy Hotel on Tuesday evening last. The machines used are similar to the latest which have been introduced into many Paris clubs and restaurants, and are worked on the "coin-in-the-slot" principle. Connection was only established with one theatre—the Savoy. Under these favourable conditions the music of the opera was heard with all purity and clearness, and with good volume of sound. The idea is to supply London with theatrophones in the same way as telephones are now provided.

Cable and Land Line Interruptions and Repairs:

Royal Institution.—The following are some of the lecture arrangements before Easter:—Dr. J. A. Fleming, three lectures on the Induction Coil and Transformer; the Right Hon. Lord Rayleigh, six lectures on Matter—at Rest and in Motion. The Friday evening meetings will begin on January 22nd, when a discourse will be given by the Right Hon. Lord Rayleigh on the Composition of Water; succeeding discourses will probably be given by Prof. Roberts-Austen, Sir David Salomons, Dr. Oliver Lodge, Prof. W. E. Ayrton, and others.—At the last general monthly meeting of the Institution the special thanks of the members were returned for donations from Prof. Dewar, for structural alterations; from Mr. Ludwig Mond, for new pressure pump.

Cable Interruptions and Repairs.—The Eastern Extension Company notifies the interruption of the Hong Kong-Manila cable. Until its restoration telegrams will be sent by post by every available opportunity. A mail boat leaves Amoy for Manila to-day (Friday). Telegrams will be posted by this mail, and if the cable communication should be restored before its arrival at Manila, they will also be transmitted by wire to their destination. The cable, together with three others in the neighbourhood, was broken by a typhoon, and the bad weather which still prevails may retard the repairing operations.—The Eastern Telegraph Company notified early in the week that communication with Zanzibar and South Africa was interrupted by both the East and the West Coast routes, but, on going to press, we learn that telegraphic communication with South Africa has been restored by the latter route.

The Standard of Light.—The Board of Trade has undertaken to appoint a committee to consider what the standard of light for testing the gas supply of London should be. The appointment of the committee has been delayed because the Board of Trade and the London County Council had no fund available for paying the expense of a committee. The South Metropolitan Gas Company have now undertaken to pay the whole of the expenses, and the committee will very shortly be formed. It will consist of two members nominated by the County Council, one by the City Corporation, three by the London gas companies, together with the three gas referees and two independent scientific men. Dr. Frankland and Mr. Dibdin, the Council's chemist, will represent the London County Council. Pending the report of this committee, the Council has deferred action in the direction of obtaining legislation for a more exact standard of light.

Obituary.—We regret to record the death of Sir Arthur Blyth, Agent-General in London for South Australia, on Monday. He was born in Birmingham in March, 1823, and was educated at King Edward's Grammar School in that town. He left England for Australia in 1839, and was engaged in business until 1861. He was subsequently elected a member of the South Australian Parliament under the new Constitution. He took a leading part in many Ministries, being three times Premier of South Australia. He was appointed Agent-General in February, 1877, on the death of Mr. Francis Dutton, C.M.G. After this appointment he received the honour of Knighthood from Her Majesty, and was created Knight Commander of the Order of St. Michael and St. George, and Companion of the Bath. Sir Arthur Blyth took an active and leading part in the negotiations which led to the rates for telegrams between this country and Australia being largely reduced, under the joint guarantee of some of the Australian colonies and the telegraph companies concerned.

An Important Water Power Scheme.—The Société des Eaux de la Dranse have at their disposal a waterfall formed by a derivation from the river Dranse, which flows into the Rhone near Martigny (Valais). The head available amounts to some 660ft., the flow being nearly 180 cubic feet per second, the power disposable at the turbine shaft being therefore about 10,000 H.P., allowing 25 per cent. loss in the turbines and pipes. The cost of canals, dams, pipes, reservoirs, &c., is estimated at £56,000. Close by there is a large expanse of level ground admirably adapted for factories, &c., and a railway line running to Lausanne. The Société invites schemes for the utilisation of 6,000 H.P. for various purposes, and more especially in connection with the reduction of aluminium, the manufacture of chlorate of potash, and electro-metallurgical works. The Société offers a first prize of £160, a second of £80, and a third of £40. The schemes must be received by midday on February 29, 1892, by MM. Cuénod-Churchill et Fils, bankers, Vevey (Vaud), Switzerland.

The Roundhay Electric Tramway and the Telephones.—At a meeting of the Tramways Section of the Highways Committee of the Leeds Corporation on Monday, a deputation from the National Telephone Company complained that the telephonic system on the Roundhay Road section was being seriously interfered with by the electric tramway current. Dr. John Hopkinson and Mr. Winterbotham, who represented the interests of the Telephone Company, pointed out that the electric current made a buzzing noise in the telephone, and that operators could distinguish when a car was on the line and when it was ascending an incline. Between 20 and 30 users of the telephone living between Sheepscar and Roundhay allege that they cannot hear anything that is said to them. Mr. Graff Baker and Mr. Winslow, who attended on behalf of the lessees of the electric tramway, replied that their wires were run and their cars worked exactly as in America. The Committee having heard all that both parties had to say, decided to leave the two companies to settle the matter between them.

Economy of an Electric Mining Plant.—In a Paper recently read before the Engineers' Society of Western Pennsylvania, Mr. C. F. Scott drew a comparison between hand labour and machine labour for coal-mining. In machine mining the stalls can be made much wider because of the greater rapidity of mining, so that the roof will stand a shorter time with fewer pillars. The immediate effect of the introduction of coal-cutting machinery is to reduce the cost of undercutting from 20d. to 5d. per ton of 1¼in. coal in the Pennsylvania district. Taking into account the other expenses, there is a saving of 25 per cent. Another advantage of machine mining is that perfect pillars are left, and can be recovered, as there is no temptation to rob them. The reduction of the number of stalls for the same output, due to machinery, also causes a great saving in the timber, the number of roads, and the tramways that have to be kept up. The saving in coal, due to the introduction of machinery, is also very great; this arises from the small amount of slack and the larger coal produced by the smaller height and greater depth of undercutting, and also from the pillars not being crushed. An estimate is given of the saving in expense

Digitized by Google

by using a plant of seven machines, run ten hours a day, and cutting 233 tons. The cost is £29. 11s. 3d., made up as follows:—Fuel, 9s. 7d.; wages, £2. 10s.; deterioration of boiler, engine, electrical apparatus, and wire, £1. 6s.; cost of repairs, £1. 0s. 8d.; cost of working, £4. 17s.; loading and blasting, £19. 8s. The indirect saving is estimated at £2. 19s. The cost of hand mining is £38. 6s. 8d. The saving by the use of machines is therefore considerable in all directions.

Chicago Exhibition.—The report of Director-General Davis upon the subject of awards and juries has been submitted to a sub-committee. The Director-General says that if the jury of awards is organised by July 1, 1893, its work can be completed substantially by August 16th, and the work of revision finished by September 1st. The number of jurors required he estimates, after consultation with the chiefs of thirteen departments of the Exposition in which exhibits will be entered, is 659. Machinery—Six juries, thirty-six judges. Electricity—Five juries, thirty-five judges. Colonel Davis also recommends that a special jury be drawn from the regular group of juries, to give an award to the exhibit showing the best and most satisfactory installation in each of the thirteen departments. Each of the judges is to be paid six dollars a day for his services, which are not to exceed forty days. Colonel Davis believes that 130,000 dollars will be enough to pay the judges. He recommends further that the policy of the Exhibition should be very conservative in respect to the number of awards, and that the authorities should study how they will be able to limit rather than to enlarge the number.——At a recent meeting of the Committee on Electricity, Electrical and Pneumatic Appliances, the following names were decided upon as those of eminent electricians not now living, to be placed over the Electricity Building at the Exposition:—Franklin, Galvani, Ampère, Faraday, Ohm, Sturgeon, Morse, Siemens, Davy, Volta, Henry, Oersted, Coulomb, Ronald, Page, Weber, Gilbert, Davenport, Soemmering, Don Silva, Arago, Daniell, Jacobi, Wheatstone, Gauss, Vail, Bain, De la Rive, Joule, Saussure, Cooke, Varley, Steinheil, Guericke, La Place, Channing, Priestley, Maxwell, Coxe, Thales, Cavendish.

The Hum of Motors.—The hum given out by motors when working under heavy loads being a matter of interest, as having a practical bearing upon the subject of "motor design," I undertook, says Mr. S. W. Huff, in the *Electrical Engineer* of New York, some experiments with a view to learning the cause of it. The motor selected for the experiment was an eight-pole machine, wrought-iron field-cores and pole-pieces, with a Gramme ring-toothed armature. When the fields were unexcited and the armature was revolved at any reasonable speed, there was no sound given out, but as soon as a strong current was sent through the fields a musical hum was heard, the note increasing in force with the increase in current through the fields, and increasing in height of pitch with the increase in speed of the armature. Not having convenient anything of known pitch, the number of revolutions was carefully noted just when the note given out was beginning to be audible, *i.e.*, when the vibrations producing this note would be about 16 per second. From a number of observations it was found that when the note given out was barely audible the speed of the armature was about two revolutions per second. Since the motor had eight poles, at the time of observation any point in the armature was passing from one pole to the next 16 times per second; and since the number of vibrations per second causing the hum corresponds exactly with the number per second of changes in polarisation of the armature, it is but natural to conclude that the change in polarisation of the armature as it passes from one field pole to the next is the cause of the musical note given out by motors. The annoyance has been often lessened by reshaping of pole-pieces. The fact that the force of the musical note increased with increase in the current through the fields would seem to show that the note increased in force with increase in saturation in the magnetic circuit taken as a whole, and that a reduction in the possible saturation through the magnetic circuit as a whole would decrease the force of the note.

The Berliner Microphone Patent.—"Rarely," says the *Electrical World*, "has a patent on any subject whatever caused so profound a sensation as the granting to Emile Berliner on November 17th of what on its face appeared to be a broad claim on the microphone transmitter now used well nigh universally wherever the telephone exists. Electrical circles were less surprised than the general public, but a feeling akin to consternation has pervaded the atmosphere during the past week. It is, indeed, an extraordinary patent, no less on account of the sweeping character of some of its claims than by reason of its remarkable history in the Patent Office. There are various lines of attack on the transmitter patent that will doubtless be assiduously followed so soon as the subject comes before the Courts. The fact is that albeit the Berliner microphone patent is broad and of unquestionable importance, it has by no means so great a value to the telephone monopoly as would make it vitally necessary that it should be sustained. A large number of subsidiary and accessory patents on telephonic apparatus of an infinite variety, as well as the commercial security assured by immense plants and important franchises, are likely to give the present telephone organisation a lease of life extending considerably beyond the expiration of the famous 1876 patent, quite independent of the transmitter now in question." In the same issue (November 28th) our New York contemporary devotes several columns to an interesting discussion of the various questions connected with the granting of the Berliner patent, and the possibility of its being upset or avoided. Elisha Gray's device for producing variations of electrical resistance by means of a vibrating diaphragm connected to electrodes placed in a minute liquid rheostat, is considered, by the *Electrical World*, as a possible anticipation of Berliner's broad claim to the production of electrical undulations by causing sound waves to vary the resistance of an electric circuit, comprising electrodes in constant contact. If it is a question of "getting round" the Berliner patent, we would suggest a trial of Chichester Bell's water-jet transmitter (see *The Electrician*, Vol. XXI., p. 375).

The Electrical Trades Section.—Speaking on Wednesday at the quarterly general meeting of the London Chamber of Commerce, Mr. Crompton (Chairman of the Electrical Trade Section) stated that his was one of the youngest sections of the Chamber. A very mistaken idea regarding the nature of electricity was abroad only a short while ago, and it was thought that it could not be dealt with on commercial principles. The public had had to be educated in all these matters. They had had to memorialise the Government to provide them with accurate standards of measurement which could be compared in Government departments in the same way as other standards; and by the action of the Chamber they had succeeded. Another important matter upon which they had used their offices to remove misconception on the part of the public had been in connection with overhead wires. Nearly everyone grumbled about the metropolis being disfigured by a network of overhead wires. There were two sides to this question, and few were aware that it was mainly the want of regulation as to overhead wires that was to blame for that about which so much complaint was heard. If those who put up these wires were possessed of Parliamentary powers they would be able to cross the streets in a compact block at intervals, and the cause of complaint would be almost entirely removed. This plan had been carried out in many Continental towns, and scarcely any disfigurement of the streets was perceptible. Their section of the Chamber had been of considerable use to the profession in connection with visits to Continental Exhibitions. Exhibitions had been a very great tax on the trade in the past few years; but, he thought, now that those conducting these Exhibitions knew that the trade had a centre in the London Chamber of Commerce, that the interests of exhibitors would be better consulted than they had been in the past. They had a long list of useful works before them. He might mention, among other things, that their trade was now proposing to begin a system of beds in convalescent homes for their *employés* who had been incapacitated from work; and he thought that this system might be usefully followed by other trades. As, however, they were themselves young and energetic, they would, perhaps, have the credit of taking the lead in this matter.

THE DETERMINATION OF CURRENTS IN ABSOLUTE ELECTRO-MAGNETIC MEASURE.

BY G. F. C. SEARLE, M.A.

(*Continued from page 118.*)

§ 35. **Action of One Current upon Another** (*see* § 21).—We have seen (§§ 20, 30) that the mutual potential energy of a current of strength i, flowing in any circuit A, and any magnetic system, is equal to $-Ni$, where N is the number of lines of induction due to the magnetic system which would pass through A if the the current were not flowing, the positive direction for the lines being that of the lines of induction due to the current itself. We have now to consider the case in which the magnetic system is another electric current of strength i'. Suppose that when no current flows in A and unit current flows in the second circuit B, M lines of induction pass through A. Then, if a current i' flows in B, the number of lines through A will be Mi', since the magnetic force everywhere is proportional to the strength of the current. If now a current i flows in A, in such a direction that its own lines of induction pass through it in the same direction as those due to B, the mutual potential energy of the two currents will be $-Mii'$. The quantity M is called the Coefficient of Mutual Induction of the Two Circuits. This expression $-Mii'$ really contains the whole theory of the mutual action of two currents, and from it all the actions between them can be deduced.

We see from the form of the expression for the mutual potential energy of the two currents, that the number of lines of induction which pass through the circuit A (when it carries no current), due to unit current in B, is equal to the number which pass through the circuit B (when it carries no current) due to unit current in A. Considering that the two circuits may be of any shape or size whatever, we must regard this result as a remarkable reciprocal theorem.

§ 36. **Number of Lines of Induction through a Circuit.**—This number N can be calculated by two different methods. The first consists in simply counting how many lines of induction pass through the circuit, the second in finding how many lines have *cut through* the circuit while it is brought up from an infinite distance to its actual position. Since a line of induction is closed upon itself, the only way in which a line can link itself with the circuit is by cutting through it. It is clear then, that by taking a proper account of the number of lines which have cut through the circuit during its journey from infinity, we shall be able to determine the number which pass through the circuit, and are, therefore, linked with it in its actual position.

§ 37. **First Method of Finding N.**—Close up the circuit by any surface S, and calculate the magnetic induction at all points of this surface. Let $\mathbf{B}$ be the magnetic induction, and θ the angle it makes with the normal to the surface at any point. The normals must always be drawn from the *same* side of the surface. Let α be any small area on the surface; the number of lines of induction passing through α is $\mathbf{B}\cos\theta\,.\,\alpha$. Taking the sum of all these quantities for the whole of the surface bounded by the circuit, we find $N = \Sigma\,\mathbf{B}\cos\theta\times\alpha$. In the notation of the integral calculus we write this $N = \iint \mathbf{B}\cos\theta\,dS$, the double integral being put to remind us that the integration is taken over a *surface*. In making this calculation we may make S of any shape we please, the only limitation being that it must have the given circuit for its boundary. Thus, if the circuit is a circle we may make S a plane or a part of a sphere, according as is most convenient for our analysis.

§ 38. **Second Method of Finding N.**—According to the principle laid down in § 36 we can find N by determining how many lines of induction cut across each part of the circuit while it is brought up from an infinite distance to its actual position, and adding all these numbers together for the complete circuit, the contribution from each part being taken with the proper sign. From any point, P, in the field draw a short straight line, P Q, in any direction. If P Q is brought up from an infinite distance to its present position, P Q always retaining a fixed direction, a definite number of lines of induction will have cut across P Q. Since the linking of a line of induction with the circuit is the opposite of the unlinking, we must have some criterion to enable us to decide when the passage of a line of induction across P Q is to be considered positive, and when negative. We shall adopt the following specification. Let an observer stand with his feet at P so that the lines of induction run in the direction of feet to head. Let him look along in the direction in which P Q is drawn. If as P Q moves along carrying the observer with it, a line of induction passes in front of the observer from right to left, its passage across P Q is to be counted positive; but if it passes from left to right, then the passage is to be counted negative. Now, the number of lines of induction which have cut across P Q per centimetre of its length depends upon the direction in which P Q is drawn, and for one direction is the greatest possible. This maximum number is called the "vector potential" at P, and is denoted by $\mathbf{A}$, while the corresponding direction is called

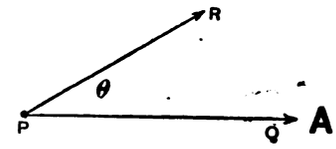

Fig. 37.

the direction of the "vector potential." Since when both the direction and magnitude of the "vector potential" are known, this quantity is completely defined, it follows that it is a vector; we may therefore apply the rules of vector analysis to it. Thus it follows at once that if we draw any very short line, P R (Fig. 37), making an angle θ with P Q the direction of the vector potential, then the number of lines of induction which have crossed P R per centimetre of its length in the positive direction, while P R has been brought up from an infinite distance to its present position is $\mathbf{A}\cos\theta$, or is the resolved part of the vector potential in the direction P R. P R is, of course, always to be kept in a fixed direction during the motion. It is also clear that if P Q is the direction of the vector potential at P, then if P R is drawn at right angles to P Q, no lines of induction will on the whole have crossed P R.

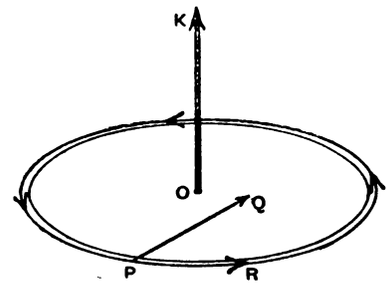

Fig. 38.

We can now write down the number of lines of induction which pass through any circuit in terms of $\mathbf{A}$. Let $\mathbf{A}$ be the value of the vector potential at any point P of the circuit (Fig. 38), θ the angle between its direction P Q, and that of the element P R ($=\sigma$) of the circuit. If we wish to find the number of lines of induction through the circuit in the direction indicated by the arrow O K we must always draw σ in the direction of the arrow P R, the two directions being related to one another in the same way as the translation and rotation of a right-handed screw. This is only another way of expressing the specification laid down above. The number of lines of induction which have cut across σ in the positive direction, while the circuit has been brought up from an infinite distance is $\mathbf{A}\cos\theta\,.\,\sigma$. Taking the sum all round the circuit we have for the total number of lines of force which pass through the circuit, or are linked with it, $N = \Sigma\,\mathbf{A}\cos\theta\cdot\sigma$. Employing the notation of the integral calculus $N = \int \mathbf{A}\cos\theta\,ds$, ds being an element of the circuit, and the integration extending all round

Digitized by Google

the circuit. We have now shown how to find N by the second method.

§ 39. Thus N can be expressed either as a surface integral $N = \iint \mathbf{B} \cos\theta\, dS$, or as a line integral $N = \int \mathbf{A} \cos\theta\, ds$. The idea involved in the expression of a surface integral in terms of a line integral was originally due to Prof. Sir G. G. Stokes,* and has led to very many improvements in the theories of hydrodynamics, electromagnetism, and other subjects involving the same type of analytical methods. The definition of the vector potential given above is really the same as that given by Maxwell; the present mode of expressing it is that given by Dr. Fleming in "The Alternate Current Transformer" (p. 352), and, as we shall see presently, leads to an easy method of obtaining Neumann's formula.

§ 40. **Vector Potential of an Element.**—We shall now show how the value of A at any point due to a current flowing in any circuit may be expressed in terms of the geometrical configuration of the circuit. Take an element of current of length σ and strength i (Fig. 39). Let O be the centre of σ. Let P be the point at which the vector potential is to be found, and let $OP = r$. Draw P Z perpendicular to the continuation of σ, and let P′ be any point on Z P, and let the angle $P'OZ = \theta$. Draw a short straight line P′ Q′ parallel to σ. Now, by § 32 we have seen that the magnetic force at P′ due to the element $i\sigma$ is $i\sigma \sin\theta / OP'^2$ at right angles to the plane O Z P′. Since we are only dealing with air this is also the value of the magnetic induction. When P′ moves through a small distance, x, towards Z, it is cut through in the positive direction by $i\sigma \sin\theta\, x / OP'^2$ lines of induction per centimetre of its length. But if a

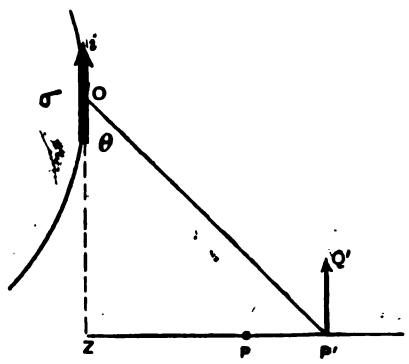

Fig. 39.

pole of strength $i\sigma$ were placed at O, the magnetic force at P′ would be $i\sigma / OP'^2$ along O P′, and the resolved part of this in the direction Z P′ would be $i\sigma \sin\theta / OP'^2$. The work spent upon a unit pole in moving it along P′ Z through a small distance, x, towards Z, is, therefore, $\frac{i\sigma \sin\theta}{OP'^2} x$, the same expression as we found for the number of lines of induction which cut across P′ Q′ per centimetre while it is moved through the distance x.

Thus we see that the whole number of lines of induction which have cut across the moving line per centimetre of its length while it is brought up from an infinite distance is equal to the work spent upon bringing up a unit pole to the same place in presence of a pole of strength $i\sigma$ placed at O. In other words, the value of the vector potential at any point, P, due to the current element $i\sigma$ at O is equal to the magnetic potential at P due to a pole of strength $i\sigma$ at O. The magnetic potential is $i\sigma / r$ (*see* § 17), and accordingly $i\sigma / r$ is the value of the vector potential at P due to the element of current at O. The *direction* of the vector potential is clearly that parallel to the element of the current, for if we had drawn P′ Q′ in any other direction, and had kept it parallel to that direction during its motion from infinity, lines of induction would have cut across any straight line drawn at right angles to P′ Q′, and P′ Q′ would not be the direction of the vector potential (*see* § 38). The form of the expression (*see* § 17) for **A** explains the second half of **A**'s name.

* Smith's Prize Examination, 1854.

§ 41. **Neumann's Formula.**—If we wish to determine the value of **A** at any point due to a current in any closed circuit, we can do this by finding the value of the vector potential due to each element of the circuit, and then adding all these quantities together by the process of vector addition. The resultant is the value of **A** at the point. It is the same as the resultant of a set of forces, each of which is the vector potential due to an element of the current. Although on account of the indeterminate nature of the action of an "element" of a current, the vector potential due to it is indeterminate; yet if we make use of the formula of § 40 in calculating the vector potential of a complete circuit, the result will be perfectly definite.

For it was shown in § 32 that the magnetic force at any point due to a closed circuit is the same as the resultant of a system of magnetic forces $i\,ds \sin\theta / r^2$ at right angles to the plane of r and ds. Each of these magnetic forces may be resolved into two components normal and parallel to the plane containing the moving line and the direction of its motion. Each component may be represented by an appropriate set of lines of induction in its own direction (*see* § 12). It is clear that only the component normal to the plane is cut across by the moving line. But the sum of the parts of any system of vectors resolved in any direction is equal to the resolved part of their resultant in that direction. Hence the actual number of lines of induction intersected by the moving line during any small displacement (this number is quite definite since it depends on the *resultant* magnetic force) is the same as the number which would have been intersected if each element of the current had produced a magnetic force $i\,ds \sin\theta / r^2$. But the

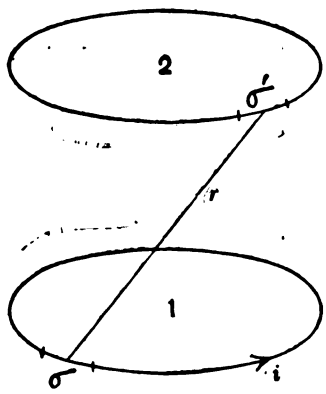

Fig. 40.

number of lines of induction belonging to any element which have been cut through by the moving line is the resolved part of the vector potential in the direction of the line. Hence the vector potential of any *closed* circuit is the same as if *each* element produced a vector potential $i\,ds/r$ parallel to ds. We may, therefore, calculate the vector potential of a closed circuit by this formula without any error or uncertainty.

We shall now find the value of N (§ 36) for the circuit (2) (Fig. 40) due to a current, i, flowing in (1). Let σ, σ' be two elements of (1) and (2), r being the distance between them Let ϵ be the angle between the directions of σ and σ'. The vector potential at σ', due to $i\,\sigma$, is $i\,\sigma/r$. Hence, the number of lines of induction which cut across σ', while (2) is brought up from an infinite distance, is $\sigma' . i\sigma \cos\epsilon . 1/r$. Thus the whole number which have cut across σ', due to the complete circuit (1), is $i\sigma' \Sigma\sigma \cos\epsilon . 1/r$, the summation taking in every element of (1). This expression is free from any indeterminateness. From this we find at once that the whole number of lines through (2), due to current i in (1), is $N = i \Sigma\sigma' \Sigma\sigma \cos\epsilon . 1/r$, the new summation taking in every element of (2). We may write this $N = i \iint ds\, ds' \cos\epsilon . 1/r$, ds, ds' being elements of (1) and (2), and the integration extending round both circuits. But $N = M\,i$, so that $M = \iint ds\, ds' \cos\epsilon . 1/r$. This remarkable formula is due to F. E. Neumann. We have seen that it expresses the whole number of lines of induction through (2) due to unit current in (1). The quantity $ds\, ds' \cos\epsilon . 1/r$, which occurs under the sign of integration, may be regarded as the

Digitized by Google

number of lines of induction due to *ds*, which have been cut across by *ds'* in its journey from infinity.

§ 42. The quantity M is called the coefficient of mutual induction of the two circuits. From the symmetry of M with regard to the two circuits we see that the number of lines of induction through (1) due to unit current in (2) is equal to the number of lines through (2) due to unit current in (1). This result also follows at once from § 35. M is clearly a quantity of the dimensions of a *line*, so that if the measurements of the two circuits are made in centimetres, the value of M will also be expressed in centimetres. When we are dealing with large coils of wire of many turns, M becomes very large when expressed in terms of centimetres, and on this account among others a larger unit is sometimes used. This unit is 10^9 centimetres, approximately the length of a quadrant of the meridian of Paris. It was thus convenient to speak of 10^9 centimetres as a quadrant. Again, since on the electro-magnetic system the ohm is 10^9 centimetres per second, the name Secohm was given to 10^9 centimetres since that is the distance described in a second by a body moving with a velocity represented by one ohm. But lately, in response to the request of the American electricians, a new name has been introduced for this quantity, viz., "the henry," as a tribute to the investigations of Prof. Joseph Henry, in the science of electro-magnetism. We shall, however, always retain the C.-G.-S. unit pure and simple.

(To be continued.)

THE FÉRY AUTOMATIC SWITCH.

The necessity of automatic switches in charging circuits, says our Paris correspondent, was felt at a very early date; and the first apparatus of this description was that of M. Hospitalier, described in *La Lumière Electrique* of June 15, 1880. This switch, however, required regulating every time the number of accumulators to be charged was altered, and it was modified later on so as to avoid this (*L'Electricien*, June 26, 1886).

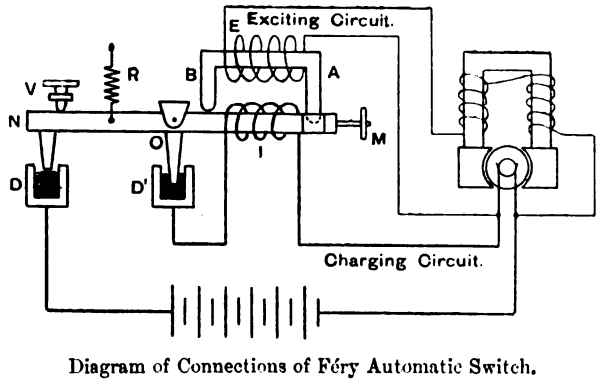

Diagram of Connections of Féry Automatic Switch.

The switch brought out by M. Ch. Féry is, for reasons of construction, of the regulating type. It consists of an iron lever N O M (see diagram), which carries two rods which plunge into the mercury cups D D' and close the charging circuit. The iron core A B is surrounded by the coil E, which is interposed in the shunt circuit of the dynamo, and the coil I is traversed by the main charging current. A spring R and a weight M, movable along a screw thread, allow the apparatus to be regulated.

When the electromotive force of the dynamo has attained its proper value, the electro-magnet A B attracts the lever N O M, which revolves around the axis O, and closes the charging circuit; the current which then traverses I helping to keep the circuit unbroken. When the speed of the dynamo is continuously reduced, the current in each coil will also diminish, and the pull of the spring R will soon preponderate, and the circuit will be broken. When the instrument is properly regulated the circuit is broken at the very moment when the current is zero.

In practice the number of cells in a battery of accumulators is often altered, and then the spring R and the weight M have to be manipulated. If by any chance this manipulation is forgotten, and the circuit is made when the volts at the dynamo terminals are less than those at the terminals of the battery, the reverse current will polarise the lever, and the circuit will be broken. The lever will then continue to oscillate like an electric bell hammer, and the attendant will be warned by the noise of the mistake. This apparatus is, therefore, a guarantee against accidents; and the strong practical shape given to it by the maker, M. Ducretet, makes it commercially useful.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

FRIDAY, December 11th. (To-day.)

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. Paper to be read:—"Meters for Recording the Consumption of Electrical Energy." By C. H. Wordingham, A.K.C., Stud. Inst. C.E.

TUESDAY, December 15th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed:—"The Sale of Water by Meter in Berlin." By Henry Gill, M. Inst. C.E.

WEDNESDAY, December 16th.

INSTITUTION OF CIVIL ENGINEERS.

2 p.m. Students' visit to the stations of the Westminster Electric Supply Corporation.

ROYAL METEOROLOGICAL SOCIETY.

7 p.m. Ordinary meeting. Papers to be read:—(1) "Report on the Thunderstorms of 1888 and 1889." By William Marriott, F.R.Met.Soc. (2) "On the Prevalence of Fog in London during the 20 years, 1871-1890." By Frederick J. Brodie, F.R.Met.Soc.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "Typological Museums, as Exemplified by the Pitt Rivers Museum at Oxford." By General Pitt Rivers,

OLD STUDENTS' ASSOCIATION.

8 p.m. Ordinary General Meeting at Finsbury Technical College. Paper to be read: "The Measurement of the Resistance of Conductors containing Disturbing Electromotive Forces, with special reference to Earth Plates." By Mr. Rollo-Appleyard, member.

THURSDAY, December 17th.

CHEMICAL SOCIETY.

8 p.m. Ordinary Meeting. Several Papers will be read.

FRIDAY, December 18th.

PHYSICAL SOCIETY.

5 p.m. Ordinary Meeting. Paper to be read: "On Interference with Alternating Currents." By H. Kilgour.

JUNIOR ENGINEERING SOCIETY.

8 p.m. Ordinary Meeting. Paper to be read: "Engineering Practice in the Cleveland and North-East Coast Districts." By S. H. Wells, Wh.Sc., Stud. Inst. C.E.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

Learned Societies in France.—According to statistics published by the Ministry of Public Instruction, there are at the present time 525 learned societies in France, of which 135 have been officially recognised as of national importance. Of these 525 societies, 95 are historical and social; 95 agricultural and horticultural; 57 medical and pharmaceutical; 45 scientific; 41 artistic; 37, geographical, and the rest miscellaneous, including photographic, statistical, and ballooning associations.

OVERHEAD WIRES AND THEIR WARDENS.

The overhead wire question is a thorn in the side of the electrical industry. Regulations, Acts of Parliament, and bye-laws beset the contractor on every side. Thirteen sections in the Regulations of the Board of Trade for securing the safety of the public and twenty-two bye-laws of the London County Council have to be observed; and the only comfort is that some of these are practically identical, and the others do not appear to clash. The Board of Trade rules, which were issued two years ago, could only take account of "conductors for the supply of energy," as their powers were limited by the Electric Lighting Acts. The bye-laws of the London County Council, under their Overhead Wires Act, deal with all wires, conductors, and cables. Some of them appear to be very stringent, but we understand that they demand little, if anything, more than the self-imposed regulations of the Post Office. The regulations of the Board of Trade were probably the outcome of a scare about imaginary dangers which were threatened by the ugly festoons that disfigured our streets. Public opinion is the true governing principle, and the Board of Trade is its instrument. It was very proper that "regulations for the public safety" should have been drawn up; and, safety being secured, the only other consideration is an æsthetic one. Æsthetic desiderata might have been attained by further rules, *e.g.*, that streets must be crossed only at definite places, at a certain minimum distance apart; and that all wires must be brought to such crossing places, and that the crossing must be at right angles. But, as a matter of fact, if safety be secured, the æsthetic question can well remain in abeyance until many other

Digitized by Google

municipal reforms have been accomplished. The Board of Trade, however, seem to have gone further than public opinion demanded. Having drawn up a set of regulations of a character quite unusual with this most practical and sensible of all Government departments, they have decided that overhead conductors can only be permitted as a temporary arrangement in rural districts as well as in large towns. In this country we have no democratic autocrat who, with a stroke of his pen, can order poles to be cut down, throwing a whole city into darkness; we do not hang wealthy citizens from lamp-posts. They do these things in republics. But the Board of Trade, following the traditions bequeathed to them by the author of the first Electric Lighting Act, continue to harass a struggling industry, and JOHN This and TOM That only quietly and by degrees drive capital out of this country.

In the absence of any control, contractors have run riot across the sky with tangled nets of cables, asking or taking way-leave here and there, and caring naught for appearance and but little for safety. This recklessness appears to have reacted in more stringency than is necessary when it is remembered that, but for a solitary accident at Brighton, no mischief whatever has been caused to the public; and this one case would have been amply provided for by reasonable care, to say nothing of the Board of Trade Regulations. To check this jungle-like growth, the Board of Trade drew up their rules, but unfortunately with but little of their usual care and forethought. We have heard that some official, we forget who, promised to some Government department, we forget which, that the working of the Electric Lighting Acts should cost nothing. All expenses would be defrayed by the fees received by the Standardising Laboratory. This condition of affairs may be reached in a few years; but at present it is as idle to expect that an efficient administration can be started on these funds alone, as it would be to hope to conduct a commercial business without a working capital. The magnitude of the electric lighting industry has been greatly under-estimated, and until recently most of the serious work was done by the already hard-worked members of the Railway Department; and even now, with an immense amount of scientific work to be done,, there is but one man, with but one assistant, to do it. A glance at "Whitaker" gives some idea of the highly-experienced and thoroughly competent men who are permanently attached to the other numerous departments of this most important Government office. If the Electrical Department had nothing more to do than the "officers appointed under the Metropolitan Gas Acts" it would still be undermanned, but it has taken upon itself duties the importance of which it apparently does not appreciate.

The bye-laws of the London County Council, which will be found elsewhere in the present issue, need not concern us much at present, though it is hardly necessary to say that we should all feel much more confidence in the Board of Trade if an efficient Electrical Department were organised, and we cannot but regret that so many of its duties are allowed to devolve on this overgrown Vestry. It is to the permanent and technical officials of the London County Council that we owe these rules, and the important movement to determine a standard of light, and it is to them that we look for a well-arranged system of certification. of meters. If they carry out these affairs as well as the Board of Trade would have done, it will not matter if the noisy part of the electorate is a mere turopolegarchy, a word which, in view of the threatened extinction of the Greek language, it may be as well to explain means government by cheesemongers. They dare not make any rules which would trouble the POSTMASTER-GENERAL, and the only matter of concern is the amount of common sense which will be applied in enforcing and interpreting them. Had these rules been made when telephone wires were first flung about among the chimneys the service might have improved more rapidly than it has pone. The nineteenth section has some grounds to support it, since it may be supposed that a "dead" wire will sooner or later give trouble. But do they do so in practice in the case of telephone wires running from an exchange to an office in which the present tenant does not employ a telephone? He, or the next tenant, may become a subscriber; and if a wire is already run up to his window some concession in the matter of rental might be entertained. At all events, to remove such a wire is only throwing away useful work.

To call attention to a point which seems to have been overlooked, and which it is by no means too late to remedy, an address, which we print in another column, will shortly be presented to the PRESIDENT OF THE BOARD OF TRADE. It is of an entirely uncontroversial character, it could not be objected to by the Committee which was consulted by the Board of Trade when the overhead conductor regulations were framed, and it touches a matter of grave importance to everyone who is interested in the development of the electrical industry, viz., the threatened prohibition of all overhead conductors, even in rural districts. This is no Chamber of Commerce matter, the address is dated from Botolph House, because that is the only common ground on which engineers and contractors can meet for such purposes. Copies of the address should find their way into the hands of all responsible men who are engaged in electrical work, and should not be treated as a mere circular, but should be signed and returned at once.

INSTITUTION OF ELECTRICAL ENGINEERS.

At the annual general meeting of the Institution of Electrical Engineers, held last night, the following members of Council were elected for the year 1892 :—

President.

Prof. W. E. Ayrton, F.R.S., President Phys. Soc.

Vice-Presidents.

Alexander Siemens.	Sir David Salomons, Bart., M.A.
R. E. Crompton, M.Inst. C.E.	Sir Henry Mance, C.I.E., M.Inst.C.E

Members of Council remaining in Office.

Major G. W. Addison, R.E.	Colonel R. Raynsford Jackson.
Sir Albert J. L. Cappel, K.C.I.E.	W. M. Mordey.
Sir James Douglass, F.R.S.	Prof. Silvanus P. Thompson, B.A., D.Sc., F.R.S.
Prof. J. A. Fleming, M.A., D.Sc.	
Prof. Geo. Forbes, F.R.SS.(L. & E.)	

New Members of Council.

Edward Hopkinson, M.A., D.Sc., M.Inst.C.E.	Prof. A. B. W. Kennedy, F.R.S., M.Inst.C.E.
Prof. John Perry, D.Sc., F.R.S.	James Swinburne.

Associate Members of Council.

Captain L. A. Beaumont, R.N.	Captain W. C. Hussey, R.E.
M. Cooper.	

It was announced in the course of the reading of the annual report that the Institution Premium had been awarded to Messrs. C. G. Lamb, E. W. Smith, and M. W. Woods, for the Paper on "The Working Efficiency of Secondary Cells," read by them in conjunction with Prof. Ayrton; the Paris Electrical Exhibition Premium being awarded to Mr. J. Swinburne for his Paper entitled "Transformer Distribution; and the Fahie Premium to Mr. P. V. Luke for his communication on the "Early History of the Telegraph in India."

The President also announced that Mr. Nikola Tesla had promised to repeat his high frequency experiments before the Institution in January.

REVIEWS.

Central Station Management and Finance. By H. H. Foster. (New York: C. C. Shelley. 1891.)

Although this little work will no doubt be of great use to engineers and managers of electric light stations in America, its contents are so directed towards the special style of business and management which is now current in that country, and which is absolutely unknown in England, that its chief interest to the English electrical engineer is to give him some insight into the details of American practice. In England electric lighting supply companies have followed the lead of the gas companies; that is to say, they supply electrical energy at certain terminals in their customers' premises, but they are in no way concerned with anything that takes place beyond this point; that is to say, they have nothing to do with the wiring of the premises other than to test it, and to see that there is no serious leakage. They do not supply or maintain the glow lamps, and very few of the companies have anything to do with arc lamps. Such few arc lamps as are run off the great London stations are in every case the property of the customers themselves, and are maintained, carboned, and repaired by them, or, in some cases, by lamp makers, who take the trouble off their hands, and agree at a contract price to keep the lamps in order and to carbon them. In America the practice appears to differ widely from this. All the arc lamps and most of the incandescent lamps are contracted for at a price per annum; and the whole apparatus connected therewith is installed by the Supplying Company in the first instance, and is afterwards maintained by them. The American Companies, therefore, have very complicated and multifarious duties to perform, and there is no doubt that for such a business a very complete organisation of workshop and storekeeping accounts is absolutely necessary to commercial success. As an aid to such success no doubt Mr. Foster's book will be a valuable contribution. It contains copies of forms, records, returns, and reports relating to circuit and dynamo tests, store-house orders, lamp renewals, and the like. It hardly contains anything of the special subject on which English engineers are anxious for information, viz., the actual working cost of producing the unit of electricity either at the terminals of the dynamo or at the consumer's lamps. The large number of blank forms attached to the book appear to have been thoroughly well thought out; but we think it a pity that they should have been reduced and printed in type of microscopic size—they cannot be read by persons of average eyesight without the use of a powerful lens.

SECONDARY BATTERIES.

BY G. H. ROBERTSON, F.C.S., ASSOC. INST. EL. ENG.

(Continued from page 123.)

The construction of a mould to produce a perforation expanding inwardly is a matter of difficulty, and therefore the grids are sometimes cast in two halves and subsequently joined, as in the Gadot

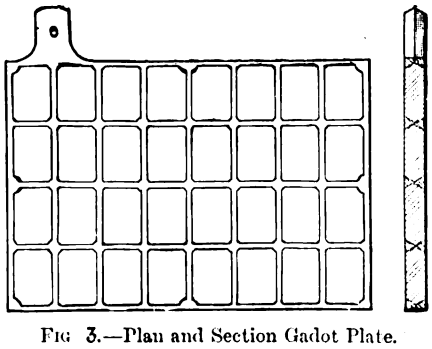

Fig. 3.—Plan and Section Gadot Plate.

cell (Fig. 3). In the Correns cell (Fig. 4), much used in Germany, the grid takes the form of a double lattice.

3. The active material is enclosed in a perforated conducting retaining vessel. In this case also the devices resorted to have been very numerous. Plain or corrugated sheets of lead have been taken and folded into boxes, either before or after applying the paste.

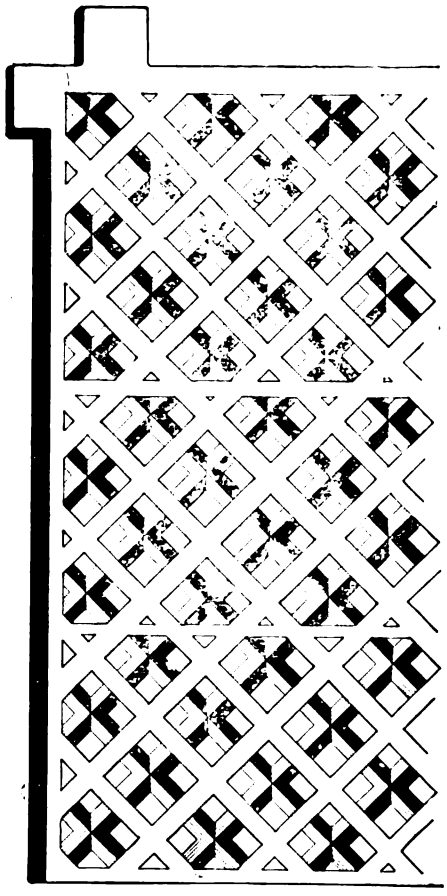

Fig. 4.—Plan Correns Double Grid.

In the Roberts cell (Fig. 5) two grids are taken, pasted on one side, and then united to form a plate with the paste inside (Fig. 6).

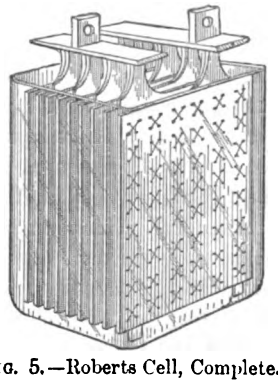

Fig. 5.—Roberts Cell, Complete.

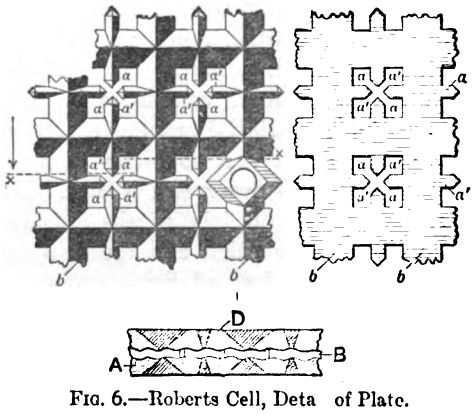

Fig. 6.—Roberts Cell, Deta of Plate.

In Dr. Tommassi's multitubular cell (Fig. 7) the retaining vessel may be constructed of metal, but is usually of some non-conducting material, and so comes under the next heading.

4. The enclosing vessel or plates are made of some non-conducting

material, or some inactive material is packed between the plates to prevent short-circuiting, and retain the active material.*

In France the plates have been covered with perforated sheets of celluloid; Reynier brought out what he called an "elastic cell," specially designed for use on torpedo boats. When tried in 1886 on board "La Gymnote" it was not a success, and the alkaline copper cell was preferred to it. Since then, however, the construction has been much improved (Fig. 8). Each cell, according to improvements effected in 1889, is composed of one positive, two negative plates, and four porous partitions, held together as shown by a frame consisting of two end plates connected together by corrugated strips of metal which have sufficient elasticity to enable them to expand and contract with the alteration in volume of the plates caused by charge and discharge (Fig. 9).

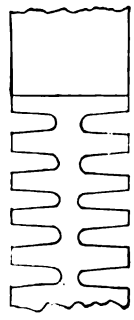

Fig. 11.

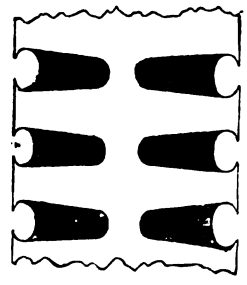

Fig. 12.

Tudor Plate, Side View, Empty.

In this country, Mr. Barber Starkey has tried filling in between the plates with a mixture of plaster of Paris and sawdust; Mr. Fuller uses porous pots; and in the United States, in the Pumpelly battery, cellulose, or wood pulp, is used to separate the plates, which are arranged horizontally as in the Atlas cell (Fig. 10).

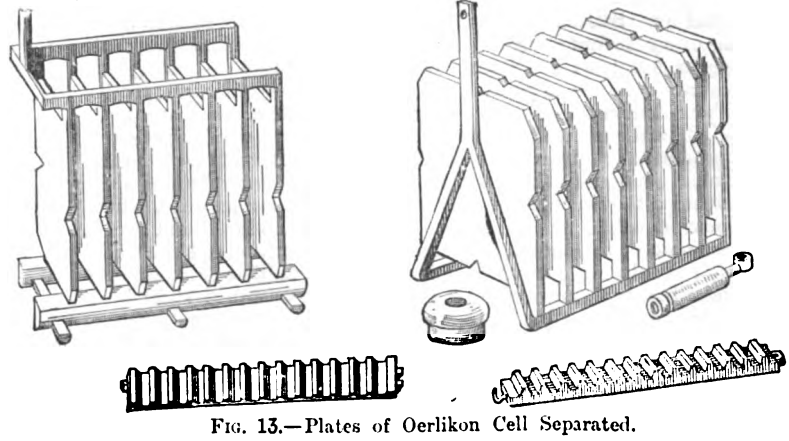

Fig. 13.—Plates of Oerlikon Cell Separated.

B. Improved Connection between the applied Oxide and the Support.—With this object the support has been well rubbed with carbon before applying the paste, and the addition of carbon to the paste in some form has been frequently recommended, as, for instance, kneading the oxides into a paste with lead acetate.

In the Tudor cell (Fig. 11) the positive plates are first treated by Planté's process to coat them with a layer of crystalline electrolytic peroxide; the grooves are then partially filled with a paste of peroxide of lead, and pressure is applied to the ridges to expand them, and partially close the mouths of the grooves (Fig. 12).

The casting or welding of the applied oxide to the plate has also been tried, and to overcome the difficulty of getting the substances to blend into one another caused by the great difference in their melting point, it has been suggested to fill the portion of the mould usually occupied by the support with some reducing agent, such as carbon mixed with nitre, so that when the fused oxides are poured into the mould they will be reduced in part to metallic lead, which will assume the place and shape of the carbon core, while the remainder forms the active material.

General Improvements.

Besides the improvements in what may be called the manufacture of the plates, or electrodes proper, various devices have been resorted to with the view of diminishing the resistance of the lugs,

* The improvements under this heading are equally applicable to cells of the Planté type, but as they are more frequently applied to cells of the Faure type I refer to them under this heading.

Digitized by Google

and securing better contact between plates of the same sign, such as making connection by tinned copper rods passed through holes in the lugs. Lead is afterwards cast round the copper, so that it is screened from the action of the acid.

Some attention has also been given to the question of the best electrolyte to use, some advocating the use of acid of density 1,150 to 1,180, while others recommend a density 1,200 and over. The addition of small quantities of some salt of the alkalies, such as sodium sulphate, or carbonate, has been recommended by Mr. Barber Starkey and others with a view of reducing sulphating; and Dr. Paul Schoop has brought out a successful gelatinous electrolyte by adding one volume of dilute sodium silicate, density 1,180, to two volumes of dilute sulphuric acid 1,250.

In order to prevent short-circuiting between the plates by the material dislodged in working, they are now either slung or rest on supports, which are so placed that the formation of a layer of mud between them is prevented.

The equalisation of the chemical action over the surface of the plates has also been attempted, and in the Schoop cell the current enters at the top of one set of plates, and leaves from the bottom of the others. The plates also are widely spaced now, as a rule, the proportion of acid to plates has been increased, and little alterations are constantly being made to secure the free circulation of the electrolyte essential to regular working.

(To be continued.)

ON THE SPECIFICATION OF INSULATED CONDUCTORS FOR ELECTRIC LIGHTING AND OTHER PURPOSES.*

BY W. H. PREECE, F.R.S., PAST-PRESIDENT.

It cannot be said that we have hitherto been happy in our mode of specifying the insulating properties of electric light cables and conductors. Standards of quality and modes of classification differ with every manufacturer. The practice of the submarine cable engineer has been continued by the electric light engineer, and cables are specified to give so many megohms per mile, irrespective of their dimensions or of the purpose to which they are to be applied; while efforts are rarely, if ever, made to verify the figures so prominently given in published tables. If tests were made, it would be found that if the results were true for one-sized conductor, they would be absolutely untrue for another. In a submarine cable, or in insulated wires for underground work, telegraphic or telephonic, the size of the conductor and the thickness of insulating coating remains constant, so that it is perfectly permissible to specify that the insulation resistance shall be x megohms per mile; but in electric light leads the diameters vary in every part of a building; a continuous mile length is rarely or never used except in mains and feeders, and the same mode of specifying is meaningless. Moreover, it is wrong; for if a conductor of 1mm. diameter gave an insulation resistance of 2,000 megohms per mile when covered with an insulator 1mm. thick, a conductor of 10mm. diameter covered to the same thickness would give only 332 megohms per mile, yet its efficiency would be the same; while, if it were constructed to give uniformly 2,000 megohms per mile, it would be absurdly constructed and wastefully paid for.

In designing an electric light lead we have to regard the insulating quality of the material to be used, and the potential differences it has to resist. Its mechanical merits we will neglect for the present. The quality of the material can be defined without reference to its form; and if it be, as it ought to be, of a uniform and consistent material, we want to know simply its *specific insulation* or its resistance to the passage of currents through it when subjected to potential differences.

Specific Resistance.

The specific resistance (ρ) of conductors is thoroughly well known. The standard of reference is the resistance of a centimetre cube of some imaginary metal whose resistance is one C.-G.-S. unit of resistance at 0 C. 1,000,000,000 (10^9) cm. of this imaginary metal 1cm.^{2} section give an ohm.

Divide 10^9 cm. by ρ, and we obtain in any metal the length in cm. of 1 cm.^{2} sectional area giving 1 ohm. Thus $\frac{10^9}{1,580} = 632,911$ cm. of soft copper of that section, and this divided by 30·48 = 20·764·8 feet, or 6,921·6 yards, which give *one ohm.*

Again, $\frac{10^9}{94,070} = 10,630$ cm. of mercury of 1 cm.^{2} section, or 106·3 cm. of 1 mm.^{2} give 1 ohm.

* Paper read before the Institution of Electrical Engineers, December 10, 1891.

The following table shows the specific resistance of various metals, together with their temperature coefficients :—

	Specific resistance.	Temperature coefficient per 1° C.
Silver	1,488	·0377
Copper (soft)	1,580	·00388
„ (hard)	1,616	·00388
Gold	2.036	·0C388
Aluminium	2.881	·0039
Zinc	5.566	·00365
Platinum	8.957	·0034
Iron	9.611	·0048
Nickel	12.300	—
Tin	13,070	·00365
Lead	19.420	·00387
German silver	20,710	·0C344
Platinum-silver	24,120	·00031
Platinoid	32.907	·00022
Nickel-steel	78.080	·0C093
Mercury	94,070	·C0086

This table also implies that if we take a length of 10^9 cm. of any metal of 1 cm.^{2} section the number (ρ) indicates the resistance of that length in ohms. Thus, 10^9 cm. of soft copper of that section gives 1,580 ohms.

Conductivity in submarine cables (of the Post Office standard type) is specified as follows:—"Each conductor shall be formed of a strand of seven copper wires, all of equal diameter, shall weigh 107lbs. per nautical mile, and shall at a temperature of 75° F. have a resistance not higher than 11·65 ohms or lower than 11·18 ohms per nautical mile."

The limits of resistance are defined in order to maintain the weight of the copper of the coils within a proper margin, and to secure the proper proportion between the metal and the dielectric. Improvement has recently taken place in the purity of the copper manufactured; the density is greater, and as a result we obtain coils which with our present mode of testing give a better result than that of Matthiessen's standard of pure copper. Coils giving 101 per cent. of pure copper are frequent, and 102 per cent. not uncommon. The manufacturers are prepared to supply pure copper; we therefore intend to abolish the percentage clause, and to abandon specifying anything but pure copper. But we must determine its specific gravity, for it appears clear that the high conductivity is due to greater density, and there is no reason to doubt the accuracy of Matthiessen's determination of the specific resistance of pure copper at a density 8·90.

Specific Insulation.

The specific resistance of insulating materials is not so well known as that of conductors, and is very variable. Clark and Sabine (1871) adopted as a standard the resistance of a cube-knot of the insulator at 75° F. (24·2° C.). But this standard never came into use, though it was tacitly admitted in all calculations derived from cylindrical cores, using the knot as unit length, and it was confined solely to submarine cables. The *knot* itself is an improper term, for a knot is a velocity, and not a length. The proper term is a nautical mile (2,029 yards) abbreviated into *naut*. Now a knot is a "naut" per hour, and is a term confined to a class. Hence its use in any form as a general standard is out of the question. A cube-kilometre, or a cube-mile, would be a more convenient unit, but a cube-quadrant (10^9 cm.)^3 is in harmony with our C.G.S. system of units now universally accepted. The *specific insulation* of any insulating material is given by the formula,

$$\sigma = \frac{\rho l 2\pi}{\log_\epsilon \frac{D}{d}}$$

where ρ is the specific resistance in C.G.S. units of the dielectric of a cable whose length is l cms., and whose insulating sheathing has inner and outer diameter of d and D respectively (D and d being in any units). The specific resistance in the C.G.S. system being that of a cubic centimetre of the material, the dimension of such a unit gives an excessive numerical value; it reads as high as 10^{25}, C.G.S. unit—a figure beyond our comprehension. A more practical dimension is the resistance of a cube whose side is 1,000,000,000 (10^9) centimetres, taken in megohms.

Since in this country it is usual (except in the case of submarine cables) to express insulation in megohms per statute mile, the specific insulation determined from this value will be given by the expression,

$$\sigma = \frac{R \times \cdot 9144 \times \frac{1,760}{10,000,000} \times 2\pi}{\log_\epsilon \frac{D}{d}};$$

Digitized by Google

or, giving 2π its numerical value and substituting common for natural logarithms, we get the expression,

$$\sigma = \frac{R \times 4{\cdot}39}{\log \frac{D}{d}} \div 10{,}000,*$$

where R is the insulation resistance in megohms per statute mile.

The practical standard, then, of specific insulation which I propose to adopt is the resistance of an earth quadrant (1,000,000,000 centimetres) cube of a certain insulating material which at 0° C. gives a resistance of 1 megohm.

In this sense the specific insulations (σ) of various materials, calculated from dimensions and resistances, but not corrected for temperature: are as follows:—

Material.	C.G.S. units.	Proposed standard. (σ)	Temperature. ° C.	Authority.
Air	∞	∞	—	—
Mica	$8{\cdot}4 \times 10^{22}$	·084	20	Ayrton & Perry.
Gutta-percha	$4{\cdot}5 \times 10^{23}$	·45	24	L. Clark.
India-rubber	$1{\cdot}09 \times 10^{25}$	10·9	24	—
Shellac	$9{\cdot}0 \times 10^{24}$	9	23	Ayrton & Perry.
Hoopers' core	$1{\cdot}5 \times 10^{25}$	15	24	Tests.
Ebonite	$2{\cdot}8 \times 10^{25}$	28	46	Ayrton & Perry.
Paraffin	$3{\cdot}4 \times 10^{25}$	34	46	" "
Glass (Flint)	2×10^{25}	20	20	T. Gray.
Siemens' special high insulating rubber	—	16·17	15	—
Siemens' ordinary pure and vulcanised rubber.	—	2·28	15	—
Siemens' specially high insulating fibrous material	—	11·60	15	—
Fowler-Waring dielectric	—	7·33	15	—
Glover vulcanised rubber	—	1·63	15	—

To obtain the true value for σ, these results, of course, ought to be corrected to 0° C.

* A simple approximation to this formula has been worked out by Mr. H. R. Kempe as follows:—

$$\text{Log}\epsilon \frac{D}{d} = 2\left\{\frac{D-d}{D+d} + \frac{1}{3}\left(\frac{D-d}{D+d}\right)^3 + \frac{1}{5}\left(\frac{D-d}{D+d}\right)^5 + \ldots\right.$$

Now, if D and d do not differ largely, we may neglect all the terms after the first without considerable error; so that the expression,

$$\frac{\rho\, l\, 2\pi}{\log\epsilon \frac{D}{d}}$$

becomes

$$\frac{\rho\, l\, \pi}{\frac{D-d}{D+d}};$$

or, substituting thickness, t, of material, we get,

$$\rho\, l\, \pi \cdot \frac{d+t}{t}.$$

Inserting the numerical value of π, and making R the resistance per statute mile, we have,

$$\sigma = R \times 5{\cdot}0559 \times \frac{d+t}{t} \div 10{,}000,$$

which may be written approximately (especially since we know that $\frac{d+t}{t}$ is actually rather too large)

$$\sigma = R \times 5{\cdot}05 \times \frac{d+t}{t} \div 10{,}000.$$

For general purposes the expression,

$$R \times 5 \times \frac{d+t}{t} \div 10{,}000,$$

or

$$\frac{R \times \frac{d+t}{t}}{2{,}000},$$

will give sufficiently correct results, being within 1 per cent. of accuracy in most cases. Thus, taking D = ·5, d = ·314, R = 5,000 (the actual results obtained with a rubber insulated wire), then t = ·093: by the exact formula we have,

$$\sigma = \frac{5{,}000 \times 4{\cdot}39}{\log{\cdot}5 - \log{\cdot}314} \div 10{,}000 = \frac{5{,}000 \times 4{\cdot}39}{\bar{1}{\cdot}6989700 - \bar{1}{\cdot}4969296} \div 10{,}000 = 10{\cdot}865.$$

By the approximate formula we get,

$$\frac{5{,}000 \times \frac{{\cdot}314 + {\cdot}093}{{\cdot}093}}{2{,}000} = 10{\cdot}941.$$

Electrification.

Insulated conductors should always be subjected to the process of electrification for one minute before the scale reading from which the insulation is to be calculated is noted. The leakage current polarises the dielectric; the insulation apparently improves—rapidly at first, then more slowly—and unless some conventional time were agreed upon for the test, proper comparisons could not be made. One minute is universally accepted as the period. The rate of fall due to electrification is a great test of the quality of the insulating material. It varies with the nature and quality of the material, being more marked at low temperatures. Unsteady electrification is a sign of an incipient fault, and perfectly irregular electrification is an indication of good material. The resistance of the dielectric apparently gradually increases, owing to the formation of an opposing electro-motive force in what is probably a liquid electrolyte. As the rate at which electrification proceeds is an uncertain quantity, and in the best material is very low, it is better to specify that the electrification shall progress steadily, without stating the rate at which it proceeds. The temperature at which the test is to be made should also, of course, be given, 75° being the usual standard.

Thickness of Insulation.

More important is it to determine and specify the thickness of the insulating coating. Two conditions determine this—the E.M.F. to be used, and the mechanical conditions of manufacture. We have also to consider sparking distances in air, especially in the case of high-pressure mains, when heat, age, accident and use cause decay and cracks, and the conductor becomes exposed through fissures. I cannot contemplate a less thickness of any material than 1 millimetre, or ·04 of an inch, for a No. 19 wire. That means that a millimetre conductor requires as a minimum a millimetre thickness of insulating coating. Now, the striking distance of a millimetre in air is over 600 volts. As the conductor increases in diameter the thickness must increase in greater ratio, not because the E.M.F. requires it, but because the exigencies of manufacture and the mechanical construction of the core demand more stuff to resist the stresses brought to bear upon it. Given a conductor with a certain thickness of dielectric able to resist the stress of x volts, the same thickness will equally resist the same voltage whatever the diameter or sectional area of the conductor.

The actual thickness to be used above the crucial thickness required for the security of those who accidentally or purposely handle the wire depends, of course, on the specific insulation, and the higher this is the less need the thickness be, and the less the mass of material used. This is a manufacturer's question; the engineer can specify only the minimum thickness. The Board of Trade rule for aerial conductors is the following:—

"Every high-pressure aerial conductor shall be continuously insulated with a durable and efficient material, to be approved by the Board of Trade, to a thickness of not less than one-tenth part of an inch; and in cases where the extreme difference of potential in the circuit exceeds 2,000 volts, the thickness of insulation shall not be less in inches or parts of an inch than the number obtained by dividing the number expressing the volts by 20,000. This insulation shall be further efficiently protected on the outside against injury or removal by abrasion, If this protection be wholly or partly metallic, it shall be efficiently connected to earth.

"The material used for insulating any high-pressure aerial conductor shall be such as will not be liable to injurious change of physical structure or condition when exposed to any temperature between the limits of 0° and 150° Fah., or to contract with the ordinary atmosphere of towns or manufacturing districts."

The two points, then, to be met are those of specific insulation and of thickness; the former determining the quality of the material, and the latter being governed by the striking distance.

It is an extremely difficult thing to arrive at a definite conclusion as to the exact sparking distance across an air space with a given potential difference. It varies with the character of the opposing surfaces; with the resistance, capacity, and electro-magnetic inertia in the circuit; with the nature of the current—that is, whether it is steady or alternating, and also in the latter case with the frequency. Sir W. Thomson concludes "that a Daniell's battery of 5,510 elements can produce a spark between two slightly convex metallic surfaces at one-eighth of a centimetre asunder in ordinary atmospheric air" ("Papers on Electrostatics and Magnetism," page 259), which means that it requires 4,928 volts to strike across one millimetre.

Warren de la Rue obtained a result very similar. Prof. Crookes, using an induction coil, takes much lower figures, and estimates the striking E.M.F, at 1mm. as 920 volts. Mr. Ferranti, using a frequency of 200, and 20,000 volts, brought the voltage down to 620.

I propose for underground and covered conductors to specify as a minimum for 500 volts or any E.M.F. under 1mm. thickness of dielectric, and ·5mm. for each succeeding 500 volts or portion of 500 volts. Thus we should have, for—

Classification.

The classification of insulated conductors is most varied and perplexing as regards the dielectric. The most systematic method is that of Siemens as regards the conductor. The pattern number gives the length in yards which has a resistance of one-tenth of an ohm; divided by 4, it gives its carrying capacity in amperes; divided by 5, it gives its weight in lbs. per mile; divided by 6, it gives its sectional area in mm²; divided by 4,000, it gives its sectional area in square inches. Nothing can be more charming. But when we come to insulation we have types G, H, J, P, Q, R, L, M, N, LL, MM, NN, LLL, MMM, and NNN—all differing in the number and thickness of layers of pure rubber, of vulcanised rubber, of "special prepared material," in taping, braiding, preserving with compound, lead, tarred jute yarn, and iron sheathing, and also in insulation resistance per statute mile in megohms at 60°.

N, NN, and NNN, are intended for 250, 2,500, and 5,000 volts respectively, and they vary in price in the ratio, 64, 79, 93.

We are, however, told that they are tested in water *when not intended for dry places*, and Messrs. Siemens show that the insulation resistance diminishes as the size of the conductor increases.

For instance, type R: "Insulated with one layer of pure and two of vulcanised rubber, taped (braided and drawn through preservative compound). Tested under water, insulation resistance from 2,000 to 700 megohms per statute mile at 60° F., according to size of wire." The words in brackets form the sole difference between types J and R!

The Silvertown Company work up by areas of conductors, advancing by twentieths of a square inch, between $\frac{1}{10}$th square inch and 1 square inch. The insulator is composed of pure rubber—their best vulcanised india-rubber. They used to endeavour to maintain a constant ratio of diameters of conductor and dielectric, but the insulation resistance now varies with size. The wires are all rigidly tested under water, and give over 2,500 megohms per mile.

But the classification into letters is as perplexing as with nearly all the other makers, except, perhaps, the Fowler-Waring Company, who have only one dielectric and one form of protection, viz., lead covering.

The Standard Underground Cable Company of U.S.A., who use Waring's compound, specify the thickness of insulation in mils. Their smallest is 31 mils., 9 mils. less than the proposed minimum. Their thickest is 188 mils., or 7·5mm., which is good enough for 7,000 volts.

This classification into types is a manufacturer's question. We cannot interfere with it, but we do earnestly hope that they will study the convenience of the user by reducing their types to the lowest possible number, but, above all, by removing from their lists the cheap and nasty.

The evil of this loose system was strikingly exemplified in a case which recently came before the law courts, when some of the ablest counsel were busily employed for several hours in endeavouring to explain what was meant by "C" quality wire, with but little result, none of the expert witnesses present being able to throw any light on the subject.

I am much indebted to different firms for the information which they have cheerfully given me to enable me to comprehend the classification, and to determine the specific insulation of the different materials they use; and as this information may be very useful, I tabulate it, and submit it herewith.

Specification.

The consulting engineer can afford to smile at classification, for he can draw up his own specifications, but it is extremely difficult even to do this without a reference to some well-known maker's class.

No wire should ever be used which cannot be subjected to a test under water. Insulated wire is supplied which is specified *to be used in dry places only*. But as this stuff is cheap, inspection is ignored, and dry places are not always dry; its general use follows: dampness and leakage result, electrolysis sets in, and the conductor is eaten away, if it is not charred or even set on fire.

It is impossible too speak too strongly on the terrible abuse of ordinary precautions which is encouraged by the manufacture of

Digitized by Google

these cheap cables. It destroys confidence, introduces danger, and discourages the industry.

A very curious practice has recently developed itself among our wiring contractors. They have asked manufacturers to reduce the over-all diameter of their insulated conductors in order to enable them to utilise the grooved boarding which they happen to have in stock. In other words, the interests of the users of the electric light are to be sacrificed to the interests of the wood-carvers!

I do not believe in danger to person in high-pressure systems when proper material is used. They are so safeguarded that any contact between primary and secondary—practically the only source of danger—leads at once to safety. I fear more danger of fire in both systems, and this more in low-pressure systems than in high-pressure ones, for they are not so safeguarded and are more open to abuse. In fact, the numerous accidents that have occurred from imperfect work on low-pressure systems has already attracted serious attention to its dangers.

I prefer, then, to specify that—

1. The copper must be pure, and such that at a density of 8·9 its specific resistance is 1,616; that is, it must comply with Matthiessen's standard of pure hard drawn copper.

2. If it is to be covered with any vulcanised material, it must be *tinned*.

3. No size smaller than No. 19 (·04in. or 1 mm. wire) is to be used.

4. No single single wire greater than No. 16 is to be used.

5. All larger sizes are therefore to be stranded.

6. The weight of copper used is to be such that the loss of volts between the distributing switch and the furthest lamp when full load is on shall not exceed 1 per cent. Hence the current which each conductor has to carry must be given.

7. The dielectric to be employed must be described, with its specific insulation, in terms of a quadrant-cube of gutta-percha at 75deg., which is taken as unity.*

8. The thickness of dielectric must be given for the different sized conductors used.

9. The various modes of preserving and protecting the insulated cables must be given.

10. Every coil should have attached to it the maker's certificate, testifying that it complies with this specification, and that it has been tested under water.†

Testing.

There are upwards of 130,000 miles of cable submerged in the ocean, and I cannot recall to mind a single fault that has occurred since 1865 through a manufacturer's defect that has escaped the probe of the tester. Every cable is most rigidly and carefully tested under water. Why do not users do the same with their electric light conductors? It would be the greatest safeguard for security.

There is a widespread impression that the insulation varies inversely with the potential differences employed, and that the higher the voltage used the more accurate the result. This is a mistaken notion. The following experiment was made to show its fallacy:—

Table showing Results of Insulation Tests of Gutta-Percha Core with various Voltages.

Number of cells. (Leclanché).	Galvanometer readings. 1st min.	2nd min.	3rd min.	Insulation after 1 minute's electrification.
				Megohms.
10	18½	16	14½	164·3
40	76	67	64	162·2
100	179	163	157	173·3
200	181 7,000 ω	168	162	168·2
300	192 4,000 ω	181	177	172·2
400	188 3,000 ω	177	173	174·1

The advantage of high voltage is that it breaks down incipient faults; but, on the other hand, if too high, it may put in faults; it is therefore advisable that the insulation be tested with a voltage, say, not less than 50 per cent., and not more than 100 per cent. above the voltage it is intended to resist.

* This can easily be deduced from its insulation in megohms per mile when the dimensions and the temperature coefficient for the material are given.

† Messrs. W. T. Glover and the Silvertown Company already do this.

THE LONDON OVERHEAD WIRES ACT, 1891.

COUNTY COUNCIL BY-LAWS.

At the meeting of the London County Council, on December 1st, the Highways Committee submitted a report containing a set of by-laws drawn up in pursuance of the London Overhead Wires Act of 1891. These by-laws, which were approved by the Council on Tuesday last, are as follows:—

In these by-laws the expression "Company" includes person. The expression "wire" includes any wire conductor or cable, any part of which is placed, or shall hereafter be placed, over any street or any part of any street, and also any wire conductor or cable placed, or intended to be placed, on or over any building or land, and situate at any point within a distance of 50ft. from any street, but shall not include any such wire conductor or cable which is placed, or may be placed wholly upon or over any railway or any land belonging to a railway company and used as a railway station, siding, or yard, or any part of any such wire conductor or cable being upon or over any railway or such land. The expression "cable" includes any covered or insulated wire when the thickness of the covering or insulation exceeds the diameter of the wire, and any number of insulated wires combined in one cable, whether stranded or separate.

1. Within three months after the approval of these by-laws by the Board of Trade, every Company owning or using or claiming power to use any wire or wires existing at the date of such approval shall, for the purpose of registration and identification, deliver to the Council and to the Local Authority in whose district the same are situate (upon a form to be obtained from the Council), full particulars of all such wires, the particulars to be accompanied by a plan showing the routes of the wires, and to give full information as to material of wires and supports, gauge of wires, mode of support, giving dimensions of poles, stays, and other supports and attachments, position of each support, date of erection and of last renewal (if any).

2. Any Company proposing, after the approval of these by-laws, to erect any wire, or any support or attachment thereto, shall, not less than 14 days before the work is commenced, deliver to the Council and to the local authority in whose district the same are situate (upon a form to be obtained from the Council) full particulars thereof, the particulars to be accompanied by a plan showing the route of the wire, and to give full information as to—material of wire and supports, gauge of wire, mode of support (giving dimensions of the poles, stays, and other supports and attachments), position of each support; and no wire support or attachment shall be erected otherwise than in accordance with such particulars and information.

3. No post or support for any wire shall be placed or erected in any street without the previous consent in writing of the Local Authority.

4. No wire shall at any point be at a less height above the ground than 20ft., or where it crosses a street 35ft., or at a less height above any building than 7ft., except where brought into any building for use in such building, or when attached to chimneys, or other parts of buildings in accordance with these by-laws.

5. Every wire shall be supported at intervals not exceeding 115 yards, unless permission in writing be obtained from the Council and the Local Authority for a longer span, but in no case shall the distance between supports exceed 140 yards.

6. Where any wire crosses a street the angle between the wire and the direction of the street at the place of such crossing shall not be less than 60 degrees.

7. Every support for a wire shall be of durable material, and properly stayed against forces due to wind pressure, change of direction of the wires, and unequal length of span; and all wires, whether conductors or suspending wires, shall be securely attached to the supports, and shall be shackled off at each support.

8. The factor of safety for all conductors and suspending wires shall be at least five, and for all other parts of the structures at least ten, taking the maximum possible wind pressure at 50lb. per square foot. No addition need be made for a possible accumulation of snow.

9. Every support for a wire shall be marked to the satisfaction of the Council in such manner as to enable inspectors to know at once to what Company it belongs. Every new support for a wire shall also have the date of erection marked thereon.

10. No support for a wire which carries more than 10 wires shall be used for the wires of more than one Company, and no support carrying fewer than that number shall, without the previous consent in writing of the Council and the Local Authority, be used for the wires of more than one Company.

11. No single support for a wire shall be used for more than 20 wires without the consent in writing of the Council and the Local Authority.

12. Cables (where used) shall be carried by independent suspending wires and attached to the same by efficient slings; no cable shall exceed one inch outside diameter and one pound per lineal yard in weight.

13. All iron or steel wires and all iron or steel supports or attachments shall be galvanised.

14. All poles supporting wires erected on buildings shall be carried on properly galvanised iron shoes and saddles, and efficiently stayed, so that in the event of a pole breaking, it shall be impossible for it to fall into any street.

15. Every support for a wire if of metal shall be efficiently connected to earth, and if of non-conducting material, shall be protected by a lightning-conductor, fastened to the support along its entire length, and projecting

Digitized by Google

above it to a height of at least 6in., such lightning conductor being efficiently connected to earth.

16. Where a wire is attached to any wall, chimney, or similar erection, a suitable angle-plate or other suitable device of iron securely fixed shall be used.

17. Every wire, together with its supports and all structural parts belonging to or connected with it, shall be duly and efficiently supervised and maintained by the Company to which it belongs.

18. No wire, support, or attachment shall or may be in such a condition that danger to the public using the streets may be apprehended therefrom; and the Company to whom such wire, support, or attachment which is in such a condition belongs, shall be guilty of an offence against these by-laws.

19. No wire or support or attachment thereto shall remain erected for more than one month after it has ceased to be in use unless the Company intend within a period not exceeding three months to take it again into use and of such intention shall give notice to the Council and the Local Authority.

20. Every Company shall give or secure access at all reasonable times for the purpose of the inspection and examination of any wire, support or attachment, and other apparatus used in connection therewith, to the Council and the Local Authority, their officers and servants.

21. Any Company which shall erect or cause to be erected any wire, support, or attachment, otherwise than in accordance with, or shall fail to comply with or shall act contrary to, any of the requirements of the foregoing by-laws, or shall deliver to the Council or the Local Authority pursuant to these by-laws any incorrect particulars or information, shall be deemed to have committed an offence against the same, and shall be liable for every offence to a penalty of ten pounds, and in case of a continuing offence to a further penalty of forty shillings for each day after conviction, provided, nevertheless, that the Justices or Court before whom any complaint may be made, or any proceedings may be taken in respect of any such offence, may, if they think fit, adjudge the payment as a penalty of any sum less than the full amount of the penalty imposed by this by-law.

22. Nothing in these by-laws shall extend to any wire placed by any person for his private use over land belonging to him or in his occupation which does not extend over any street, and is so constructed and placed that neither the wire nor any support thereof or attachment thereto would be liable to fall into any public street.

THE ELECTRIC LIGHTING ACTS, 1882 AND 1888, AND OVERHEAD WIRES.

The following important circulars have been sent out by the Electrical Trade Section of the London Chamber of Commerce :—

DEAR SIRS: We enclose four copies of an address to the President of the Board of Trade, in consequence of that Department having recently addressed several firms engaged in electric contract work, informing them that overhead wires will in no case be allowed as a permanency. If you agree, as we think you will, in the reasonableness of the requests set forth in the address, we shall be glad if you will sign and return a copy on behalf of your firm, and further obtain the separate signatures of as many of the members and *employés* of your firm as are of standing in the electrical or engineering profession. It would be well that such of the signatories as belong to scientific institutions or societies denote the fact by attaching the usual letters after their names. We shall be glad to supply you with further copies of the address if required.—Yours faithfully,

R. E. CROMPTON (Chairman Electrical Trade Section).
KENRIC B. MURRAY (Secretary).

December 1 1891.

ADDRESS

To The Right Honourable Sir MICHAEL HICKS-BEACH, Bart., M.P.,
President of the Board of Trade, Whitehall, S.W.

"SIR,—We, the undersigned, electrical engineers, electrical contractors, and others interested in the distribution of electrical energy, have the honour to address you on the subject of the Electric Lighting Acts of 1882 and 1888, and desire respectfully to submit to you the following observations on the subject of the use of overhead conductors in rural districts.

"We are aware that in the case of the metropolis and of large towns your Department has already decided that overhead conductors can only be permitted as a temporary arrangement, and that all permanent conductors must be laid underground. Whilst we are of opinion that that decision may even yet have to be reconsidered in the light of subsequent experience, we are anxious to make it perfectly clear that in this communication we have no wish to question the correctness of that decision, but we desire to emphasise the fact that a marked distinction exists between undertakings which are to be carried out in the metropolis, in large cities or towns, and undertakings in small provincial towns or rural districts; and we beg leave to submit that, however cogent may be the reasons which have led your Department to decide against overhead conductors in large towns, such reasons do not apply with the same force in small towns or in rural districts. The objections to overhead conductors, based upon the inconvenience to traffic and the danger to life, are, in the country, far less serious, if not altogether absent; whilst, on the other hand, the advantages which such conductors afford are greater.

"As regards the safety of the public—a consideration to which, as we are aware, your Department is always bound to attach the utmost importance—we would submit that absolute prohibition of the use of overhead conductors is not necessarily consistent with increased security to the public. When overhead conductors are erected in conformity with well-considered regulations, and under proper supervision, the possibility of danger resulting from their use is so remote that it may be disregarded in view of the advantages gained. It may, in fact, be less than would be occasioned by the use of the underground mains.

"With regard, on the other hand, to the advantages which are offered by overhead conductors, we would point out that in the case of small towns and rural districts the probable consumers of electric light will (at first, at any rate) be situated at relatively considerable distances apart, and consequently undertakers will have to use long stretches of conductors in order to reach such consumers; and this they can only afford to do by the use of overhead conductors. We are of opinion, therefore, that unless new discoveries should enormously reduce the cost of the work, to an extent which at present we see no reason to anticipate, it will be a practical impossibility to introduce electric lighting in country districts except by means of overhead conductors; therefore, the adoption of a fixed rule that all conductors must be carried underground, would mean an absolute prohibition of electric lighting in such districts.

"Another and almost equally important question arises out of the use of electricity for motive purposes. We are of opinion, that for the purposes of electric traction in rural districts, overhead conductors will be found to be the only mode on which long lines can be made commercially successful, and that a fixed rule, which forbade their use throughout the United Kingdom would seriously retard the development of electrical motive power.

"In view of these circumstances we respectfully urge that your Department should not lay down as a settled principle that no overhead conductors should be allowed; but that, in the rural districts at least, the circumstances of each particular case should be allowed to determine whether overhead work should or should not be sanctioned.

"In conclusion, we beg leave to say, that while we concur in the view that the use of overhead conductors should be regulated as stringently as the public interests may require, we think that the electrical engineering industry should not be hampered by their being unconditionally forbidden; and we submit that wherever in small provincial towns or rural districts the undertakers are able to satisfy your Department that underground work would mean prohibitive expense, or for any other reasons would be impracticable, and that the objections to overhead conductors would be so slight that they might be disregarded, sanction should be given to the erection of overhead conductors, subject to such regulations and restrictions as experience may show to be necessary.

"December, 1891."

THE ECONOMIC LIMIT OF LARGE-POWER UNITS.*

BY "CARLETON."

This subject has always been one of deep interest to all persons interested in electrical development, and many electrical engineers have in no way changed their views from the first concerning the size and style of engine for electrical requirements. The vital question to be considered by electrical promoters is not what a steam horse-power costs at its station, obtained from an improved and complicated engine designed to show at its official trial a unit, for a pound, and a fraction of a pound, of coal; but what does it cost to produce light commercially at the permanent location of the lamp.

Take, for example, the long-stroke, slow-speed, direct-acting, compound or triple-expansion engine, with its multiplicity of valves and intricate connections. Floor area in places where real estate is of great value becomes the first consideration. Then multiplicity of parts increases the liability of disaster, while variation of load produces internal condensation of steam in the cylinders, caused by constantly changing temperatures, resulting in direct loss, showing a consumption of coal per horse-power per hour in the majority of direct-acting engines to be over 5lb.

Electric railway work is proving to be the most severe problem the steam-engine builder ever contended with. Rolling and saw mills were thought to be very exacting in their requirements; but now the yielding of steel and iron billets in their semi-fluid state when entering a train of rolls, as well as the entering of the circular or band saw into the log, passes out of mind when the engine-builder knows and realises that many times during the day the majority of street cars on an electrical railway start and stop simultaneously. These conditions produce a blow on the piston of the engine, which is communicated to the cross-head pin, crank pin, main bearing, and then to the dynamo through the belt. As long-stroke slow-speed engines, with an independent cut-off for the valves, run with but little if any compression in the cylinders, there is nothing to relieve this sudden blow which occurs twice during each revolution, and the result is quickly seen in the bearings of reciprocating parts, as well as the disintegration and unreliability of belts. The lining

Digitized by Google

metal of the various boxes, which is comparatively soft, yields to the violent and sudden stress put upon it, necessitating frequent driving of keys and adjustment of quarter boxes, accompanied by heat from excessive friction, not only resulting in loss of power, but in increasing the cause of expense and chances of disaster.

It is to be regretted that numerous electrical engineers are for the sake of personal advancement constantly bringing forward, at the expense of the shareholder, new and untried experiments in special engines. The compound non-condensing engine has had quite a run, much to the disgust of the shareholder, who finds with variable load and pressure the direct-acting non-condensing engine is more economical. As the electrical engineer is without financial responsibilities, the burden of loss is not with him. It is well known that the Corliss Steam-Engine Co., and the Armington and Sims Engine Co., Providence, R. I., builders of long-stroke, slow-speed, and short-stroke high-speed engines, respectively, refused to build non-condensing compound engines. Comment is unnecessary, unless it be to say that these well-known builders are more friendly to the electrical shareholder than his electrical adviser.

The various triple-expansion engines which are now attracting considerable attention have not yet been long enough in operation to judge of their fitness for central-station work. They possess many of the objections before mentioned, and their greatest claim for superiority is based on their economical running. The measure of economy of the steam-engine is determined on the consumption of steam per horse-power per hour. The builder cannot always guarantee the amount of coal to be used in developing a certain amount of horse-power, as more boilers evaporate seven pounds than nine pounds of water to a pound of coal, while some of the builders of safety water-tube boilers claim an evaporation of ten and even eleven pounds of water to a pound of coal.

If the required favourable conditions can be given to the properly proportioned and constructed triple-expansion engine, viz., constant pressure, load and speed, then its economical performance cannot be surpassed; but vary the conditions, as in electrical railway work, and the results must be anticipated by the practical manager, without mechanical knowledge. Many of the modern fast ocean steamships claim to produce a horse-power with their triple-expansion engines for from 1½ to 1⅞ pounds of coal; but as a round trip of these steamers costs $75,000, and the consumption of coal is 300 tons per day, it is, of course, impossible to obtain reliable data, and the result given is arrived at by estimating. From the Navy Department *Intelligence Series* we find it is customary to estimate the amount of coal consumed on the new cruisers. How can it be otherwise, as facilities for weighing cannot be had? There is, however, the published result of one steamship trial worth repeating. The builders claimed a horse-power for their engines of one and one-half pounds of coal. Permission was asked by a professor of a technical college to ascertain if possible the truth of the statement. It was freely given, possibly because it was thought impossible. The ship and engines were reported to be in first-class order and condition. The professor and about twenty assistants carried on their experiments, and after a continuous run of eighteen hours, actual results showed a horse-power for two and one-fourth pounds of coal. A claim was then made that the ship and engines were not at their best, but would soon be made so, and an invitation to repeat the experiments was given and accepted. Nearly three years have passed since the first trial, yet the professor has never been asked to continue his investigations, and he never will be although he obtained and gave as reliable data commercial results. They were not wanted. In case of warm bearings, or breakings of parts of the steamship engines, it is an easy matter to slow down, and if necessary to stop for an hour or two, but not so with the triple-expansion street railway engine, with more than double the number of valve-gear parts. *It must not stop.*

Electrical engineers from abroad say we are three years behind them in electrical development, and claim that our large unit system of engines, with belt transmission, is also three years behind modern progress, although these large engines in some parts of the country have not yet started. Let us hope for their success.

To say that the high-speed high-pressure engine meets all requirements would be absurd, yet it must not be denied that this class of engine has made rapid advancement when it is known that the builders of the first successful high-speed engine in this country were compelled about ten years ago to lay aside for two years their inventions and improvements, owing to intense and not well-founded opposition. It is this class of engine that has more than contributed to doubling the horse-power of the world, at the same time compelling the builders of every known kind of engine to run it faster, and improve its design and workmanship. It has compelled boiler-makers to use better materials and improve their workmanship, as higher pressures are demanded. It has not only been the means of improving the standing of mechanics, materials and engineers, but it was the pioneer engine that gave commercial electricity its first start, enabling it to get a foothold.

The credit of bringing the high-speed engine into electrical prominence, although a matter of necessity, belongs to Mr. Thomas A. Edison. Seven of the "Jumbo" combinations are still running in a central station in Milan, Italy, and although antiquated, give proof of the wisdom of the first thoughts of Mr. Edison, that should have been enlarged on by his less able and erratic followers and assistants. Another pleasing and successful illustration is the Thomson-Houston multipolar dynamo directly connected to the double upright high-speed engine for ship lighting on the Government cruisers and merchant steamers. A large number have been built, and the combination grows in favour on its merits.

Why not continue and proceed on this line of advancement, arriving at the extreme power unit of the future for large central and piston speed of 600 or 750ft.? Stroke should be 18 or 20in., stations, which is to be a compound condensing engine of 500 H.P., with a speed of not less than 200 revolutions per minute, which will permit of direct-acting, positive valves, without complication. Armatures should be part of the engine shaft, of as great a diameter as practicable to compensate for the absence of driving pulleys or balance wheel, a most essential requisite. Simplicity reduces to a minimum the liability of disaster.

Two of these extreme units would not be suitable for a station of 1,000 H.P., as a number of these combinations of various powers should be placed in each station, and if water for condensers cannot easily be obtained at small expense, then use the direct-acting engine, as about 25 times the amount of water pumped into the boilers for a certain load is required for the condensers. As the engine and dynamo duty increases, add to the present requirements another unit, and when decreasing, take from it permanently, at the same time stopping all expense of that particular unit without destroying its efficiency as a reserve factor.

The managers of small stations should not be carried away with the one gas-holder theory, but build wisely and well for their patrons and shareholders.

LEGAL INTELLIGENCE.

Anglo-American Brush Electric Light Corporation v. King, Brown and Co.

In the House of Lords on Thursday last week, the case of the Anglo-American Brush Electric Light Corporation (Limited) v. King, Brown and Company came before the Lord Chancellor, Lord Herschell, Lord Watson, Lord Macnaghten, and Lord Field, in the form of an appeal from the judgments of the Lord Ordinary and the First Division of the Court of Session, Edinburgh, revoking the appellants' letters patent.

The Attorney-General, Mr. Moulton, Q.C., and Mr. J. C. Graham appeared for the appellants; while the Solicitor-General for Scotland and Mr. Daniell represented the respondents.

The ATTORNEY-GENERAL, on behalf of the appellants, said this was an appeal from the First Division of the Inner House, Edinburgh, affirming the judgment of Lord Trayner, whereby he ordered the appellants' letters patent to be revoked. The case originally came before the Scotch Court in the form of an action by the respondents, Messrs. King, Brown and Co., carrying on business at Rosebank Works, Broughton-road, Edinburgh, against the appellants, to revoke the letters patent on the ground, amongst others, of want of novelty. The letters patent in question were granted in 1878 to Mr. Herbert John Haddan, for certain "improvements in apparatus for the generation and application of electricity for lighting, plating, and other purposes." The invention was a communication from abroad by Mr. Charles Brush, of Cleveland, Ohio, in the United States of America. The letters patent were now vested in the appellants, and were known as Brush's letters patent. The invention related to improvements in dynamo-electric machines. The third claim of the patent related to the commutator. Lord Trayner was of opinion that, though as a mechanical arrangement it was new and useful, and not open to challenge, yet that, inasmuch as it was not foreshadowed in the provisional specification, the letters patent were invalid. The fourth division of the description of the invention related to the maintenance in dynamo-electric machines of a "magnetic field." This part of the invention was commonly known as "compound winding," and was generally referred to as such in the evidence. The Attorney-General then proceeded to explain to the Court the meaning and respective advantages of series, shunt, and compound-winding. Lord Trayner and the other Judges of the Inner House decided that the claim for the latter was invalid, by reason that compound-winding had been published, firstly, by the publication of a specification filed by Mr. Samuel Alfred Varley, in pursuance of letters patent granted to him in 1876; and secondly, by the use and exhibition at Messrs. Siebe and Gorman's Works in London, in or about the year 1877, of a machine invented by Mr. S. A. Varley. With regard to the portions of Mr. Varley's specification which were relied upon by the respondents as a prior description of "compound-winding," he (the Attorney-General) submitted that this description was not a description of "compound-winding," as described and claimed by Mr. Brush, and would not have been understood as such prior to the date of Mr. Brush's patent, and that it was vague and misleading, and not sufficient to instruct the public how to perform the invention to which it was by the respondents alleged to relate. The other anticipation of Haddan's claim for compound-winding was the machine used at Messrs. Siebe and Gorman's Works in London. Mr. Gorman's evidence

Digitized by Google

and that of his foreman, Mr. Myers, was to the effect that a machine was made somewhere about the beginning of 1878; that it was tried on several occasions, on each of which alterations had to be made on it; that subsequently it was laid aside in a place in the works used for storing brass, where it was left unnoticed and untouched until about a year prior to the trial of the action. He (the learned counsel) maintained that as to this machine it was not proved to have been used as a compound-wound machine; that the user of the machine, such as it was, was not a user in public, and that the machine was an experimental one; and the experiments having failed, it was laid away and treated as an abandoned experiment, and that it was, therefore, not such a prior user as would render the claim invalid for want of novelty. He submitted that the judgments appealed from were erroneous and contrary to law, and ought to be reversed on the grounds that the letters patent were always, and now were, valid in all respects; that the specification of Mr. S. A. Varley of 1870 did not contain a description of compound winding, and did not anticipate the invention claimed by Brush in the letters patent in question; that the machine made at Siebe and Gorman's works was an abandoned experiment, and not a compound-wound machine, and was not published, and was not a publication of compound winding as claimed in Brush's specification; that the commutator claimed and described in Brush's specification was duly and sufficiently foreshadowed and comprised in the provisional specification, within the meaning of the law relating to letters patent; and that none of the objections to the validity of the letters patent relied on by the respondents were proved or capable of proof.

The hearing of the case was adjourned.

FRIDAY, DECEMBER 4TH.

The ATTORNEY-GENERAL, in continuing his arguments in support of the appeal, said the respondents alleged that "series-shunt" or "compound-winding" was described in the patent specification, No. 4,905 of 1876, by Mr. Samuel A. Varley, in terms sufficiently clear to enable the ordinary skilled workman to make it, that a dynamo-electric machine containing the series shunt-winding had been manufactured under the directions of Mr. Varley prior to the date of the alleged letters patent, and that the machine had been publicly used for the production of electric light for the business purposes of Messrs. Siebe and Gorman, submarine engineers, London, in 1877. He contended that the machine at the works of Messrs. Siebe and Gorman was an abandoned experiment, and not a publication of compound-winding as claimed in Mr. Brush's specification, and that Mr. Varley's specification, No. 4,905 of 1876, added nothing to the then existing stock of public knowledge. The learned counsel had not concluded his arguments when the Court adjourned till Monday.

MONDAY, DECEMBER 7TH.

The ATTORNEY-GENERAL, in resuming his arguments in support of the appeal, again dealt with the point as to the publication of the machine made at the works of Siebe and Gorman, and used in 1877 to enable a photograph to be taken of an ice-making machine. He submitted that after experiments were made with it it was put aside and abandoned, and that there was never any publication.

Lord WATSON said the persons who saw it knew only that it was a machine used to produce electric light.

The ATTORNEY-GENERAL remarked that that was so. He went further, and said that whatever happened the inventor himself abandoned the machine.

The LORD CHANCELLOR said it was possible that the inventor would not have thought of it again but for the fact that the incandescent lamp was invented a year or two afterwards.

The ATTORNEY-GENERAL, in conclusion, submitted that the Brush patent was valid on the ground that there was no sufficient description of a shunt-series machine in Mr. Varley's patent, and that Mr. Brush's disclosure was the first made on the subject.

Mr. MOULTON, in following on the same side, said the proper mode of deciding this question was to ascertain what was the precise invention in question, and whether it was or was not fully disclosed in Mr. Varley's patent. He desired to direct their Lordships' careful attention to the first question, namely, which was the precise invention. There had been many approaches up to the complete perfect invention. His case was that Mr. Varley did not disclose anything new. He simply described the first and second steps to be taken in arriving at the perfect invention, but he said nothing about the third and final step; therefore, he added nothing to what was the admitted stock of knowledge at that date. The third step which produced compound winding was not in any way disclosed by Mr. Varley's specification. Series winding was known, and self-excitation was known; and Mr. Varley's specification brought before the mind of persons reading it that the mode of constructing the machine was to have two external circuits, both of them going round the magnets, but coming from separate bobbins of the machine.

The LORD CHANCELLOR: Separate sources of electricity.

Mr. MOULTON: Yes. That method, however, did not give the compensation which was the real value of compound winding. In the case of the shunt there was only one wire round the magnet, and there was only one external circuit. The exact invention that Mr. Brush made was to allow the two circuits going round the magnets to have a common part—not to be complete circuits, but to have the power of interfering with one another. That was the third step which was taken by Mr. Brush, and not by Mr. Varley. He submitted that the words used by Mr. Varley in his specification described a then existing arrangement which was not compound winding, and to which something must be added to make it compound winding.

Mr. MOULTON, continuing, said Mr. Brush seemed to have made his machines in America before the date of his patent. With the shunt series one could not fail to get compensation. Mr. Brush had put into the hands of his opponents a method by which they could obtain compensation, and, therefore, he was entitled to the merit of that compensation. As to the alleged prior publication, he submitted that there was not a sufficient user of the machine made at Messrs. Siebe and Gorman's works to acquaint the public of the invention.

The LORD CHANCELLOR: But when it was used do you say it was not used as a series-shunt winding machine?

Mr. MOULTON: Not at all times.

At the conclusion of the learned counsel's arguments their Lordships intimated that they would consider whether it was necessary for them to hear the Solicitor-General for Scotland on behalf of the respondents.

John Denby v. Ernest Scott and Mountain.

Judgment was pronounced in the Court of Session on Wednesday by Lord Kyllachy in the action by John Denby, stereotyper and electrotyper, 4, Swinton-row, Edinburgh, against Ernest Scott and Mountain (Limited), engineers, Close Works, Newcastle-upon-Tyne, for £500 damages for alleged breach of contract. The pursuer stated that up till the end of the year 1890, or the beginning of 1891, the defenders' business was carried on under the name of Ernest Scott and Co., and thereafter under the name of Ernest Scott and Mountain. Ernest Scott and Co. had exhibits of their electrical manufactures, and in particular of dynamo machines, at the Edinburgh Exhibition of 1890. In June of that year the pursuer purchased a dynamo for the specified and particular purpose of being used in his business as an electrotyper. It was delivered about the middle of September, and was properly fitted up; but pursuer averred that it turned out unfit for the particular purpose for which it was furnished, in respect that—(1) it was constructed both for the purpose of nickel-plating and electrotyping—a dynamo constructed for nickel-plating not being suited for electrotyping; (2) the dynamo was much too powerful for electrotyping, and caused the deposit of copper to take a granular form instead of presenting a smooth, tough surface; and (3) it could not produce an electrotype sooner than 12 or 14 hours, whereas it should produce one within from three to five hours according to the quantity of moulds in the bath. The purchase price of the machine was £55, and the pursuer stated that through its breakdown he was unable to execute a large order, and that his business suffered in other respects on account of the bad work it produced. The defenders denied that they entered into any contract with the pursuer. They explained that at the end of December, 1890, they purchased the business carried on at Close Works by Ernest Scott and Co., and were now carrying on the same. The machine, they said, was not supplied by their predecessors for any particular purpose, nor did the defenders assume any responsibility or liability in respect of any contract entered into with the pursuer. The defects in the dynamo were said to have been due to insufficient fitting up, lack of knowledge on the part of the pursuer, want of skill in manipulation, and to the absence of necessary instruments.

At the proof, which was led some time ago Mr. Ure, Mr. McLennan and Mr. Daniell, instructed by Mr. Thomas Liddle, S.S.C., represented the pursuer; while Mr. Asher, Q.C., and Mr. Watt, instructed by Mr. David Hunter, S.S.C., represented the defenders.

Lord KYLLACHY, holding that the pursuer had failed to prove his case, assoilzied the defenders, and awarded them expenses.

In giving judgment, his LORDSHIP said he did not feel altogether sure about the decision in this case. Long as the proof had been, it had not quite cleared up the mystery which he thought still surrounded the history of this dynamo. His Lordship had, however, after carefully reading the correspondence and the evidence, come to the conclusion that he must find for the defenders, on the ground that the pursuer had not proved that the dynamo in question was disconform to contract. He did not propose to state his views on the evidence in detail, but he might give some of the points on which he had formed his opinion. In the first place, his Lordship was disposed to accept the pursuer's reading of the contract, viz., that the defenders undertook not merely to supply a dynamo answering the description of No. 5, class 6, but they also guaranteed that the machine furnished was suitable for electrotyping, and would, under proper conditions, and worked by the pursuer's gas engine, particulars of which were given, produce a satisfactory deposit of copper. He did not think, indeed, that this was seriously disputed by the defendants. At any rate, his Lordship had little doubt that their undertaking went thus far. In the second place, he thought it was equally clear that the dynamo which the pursuer furnished did not, when supplied to the pursuer's works and tried practically over a period of some months, give satisfactory results. On the contrary, it was, his Lordship thought, clear that the results were hopelessly bad; and that the pursuer, after trying everything he knew, and everything the defenders suggested, was unable to effect any improvement, the result being that his business, if not destroyed, was greatly injured, and he suffered in various ways serious loss and damage. Now as to the cause or causes of this failure. The direct and positive evidence was not at all satisfactory. He could not say that the defenders had succeeded in establishing any definite fault as against the pursuer's bath, or the solution, or his manipulation of his bath. So far as appeared, the pursuer worked throughout in the same manner as he had successfully worked his battery; and experienced electrotypers, such as Mr. Clyde, whom he called in, found nothing wrong with his methods; and the defenders, in their correspondence, suggested nothing wrong. Their complaint was that the pursuer expected quicker work with the dynamo than with the battery, an expectation which, according to Mr. Fairfoul was entirely right. Mr. Low said he suggested that the pursuer had too weak a solution, but he did not mention this in his correspondence with his principals, and nobody suggested the main complaint, the granulated character of the

Digitized by Google

deposit. It was true, also, that one of the defenders'witnesses, Mr. Fairfoul, condemned the use of acid in the solution when a dynamo was being used, and the whole difficulty might have been due to that cause; but all the other witnesses approved of the use of acid, although some of them appeared to hold that with a dynamo less acid should be used than with a battery. Altogether his Lordship was bound to say that the defenders, if the onus rested on them, had not, in his opinion, succeeded in explaining the admitted failure of the results by anything to which they could point connected with the pursuer's bath or of his methods of manipulation. It remained, however, to consider whether the pursuer, on whom the onus primarily lay, had been able to prove affirmatively that there was something wrong with the defenders' dynamo. It was not enough for the defenders to say that there was no proof of anything wrong with the bath. The fault might have been there, although no particular fault could be proved. The pursuer must, in order to succeed, show that there was something wrong with the dynamo. Now, his Lordship was bound to say that, apart from the proved results of the recent trials of the machine in Mr. Goskirk's and Messrs. Chambers' works, he should have been, on the whole, inclined to hold that the balance of the evidence was against the suitableness of this dynamo for purposes of electrotyping. He meant that, apart from the trials referred to, he should have been inclined to conclude that this dynamo was of too high a voltage, or electromotive force, for electrotyping, and that for some reason it did not admit of having its voltage reduced by the usual expedients, or reduced so as to give a good result. But, then, these recent trials, if they were to be trusted, appeared to demonstrate that the voltage was not too high, but quite suitable; and that this identical dynamo, worked in connection with ordinary baths, and under ordinary conditions, had repeatedly produced electrotypes to which no fault could be found, and which, indeed, were admitted to be of exceptional excellence. The evidence of Mr. Fairfoul, Mr. Mackay, and Mr. Goskirk all seemed to establish that beyond doubt. Unless, therefore, there was some reason to believe that the dynamo, as it now stood, had been in some way altered, and was not now in the same condition as it was when it left the pursuer's works, his Lordship had not been able to see any escape from the conclusion that, whatever might have been wrong with the pursuer's results, the fault was not in the dynamo; and, that being so, the question was brought to this—was he to believe or disbelieve the defenders' evidence on this subject? His Lordship confessed, when it was so put, that he hesitated to come to the conclusion that—contrary to the testimony of Mr. Mountain, concurred in by Mr. Rolfe, and not impugned or contradicted by any direct evidence to the contrary—the defenders were guilty for the purpose of defeating the pursuer's claim of a gross and deliberate fraud; that was to say, that they altered previous to the trials in Edinburgh the armature or other parts of the machine. It was no doubt unfortunate that the machine having been returned to the defenders' works, he thought in April, remained at these works in Newcastle until September, when it was again sent down to Edinburgh to be tried at Mr. Goskirk's works; but his Lordship could not say that that was in his opinion sufficient, as the pursuer suggested, to deprive the recent trials in Edinburgh of all value. His Lordship thought, difficult as the whole case was, that it was on the whole more probable that there was something wrong with the pursuer's management of his bath or management of his gas-engine, than that the dynamo, which worked so well now, was a different machine from that supplied to and worked by the pursuer. On the whole, therefore, he had come to the conclusion that the pursuer had failed to prove his case, and that the defenders must be assoilzied with expenses.

International Cable Company (Limited) v. Suren, Hartmann and Co., and W. T. Henley's Telegraph Works Company (Limited).

In the Chancery Division on Tuesday, Mr. Justice Mathew had before him the case of the International Cable Company (Limited) v. Suren, Hartmann and Co. and W. T. Henley's Telegraph Works Company (Limited) (third parties, which was an action brought by the International Cable Company to recover £250 and £1,000 payable in respect of shares which had been applied for and allotted in the plaintiff Company. The Company was incorporated in 1886. Application was made by Messrs. Suren, Hartmann and Co. in the usual form, the issue being made upon a prospectus which mentioned the capital to be £1,000,000 in 100,000 shares of £10 each. Upon the first issue 10s. was payable on application, 10s. on allotment, and £2 at the expiration of one month from allotment. The 10s. on application was paid, and the £250 due on allotment had been paid since the action, so that the claim related now solely to the £1,000 in respect of the £2 call. The issue was between Messrs. Suren, Hartmann and Co. and Messrs. W. T. Henley's Telegraph Works Company (Limited), who were brought before the Court upon a third party notice. Messrs. Suren, Hartmann and Co. claimed to have been indemnified by Messrs. Henley's Telegraph Works Company under the terms of an agreement which had reference to an anticipated order for the manufacture and laying cables between Lisbon to the Azores, and thence on to the American coast. The International Cable Company (Limited) is in liquidation, and the list of contributories was stated to have been settled by certificate of the Chief Clerk.

Mr. Graham Hastings, Q.C., and Mr. Grosvenor Woods appeared for the plaintiff company; Mr. Phipson Beale, Q.C., and Mr. J. W. Baines for the defendants; and Mr. W. F. Robinson, Q.C., and Mr. Row for the Henley's Telegraph Works Company.

His LORDSHIP, at the conclusion of the arguments of the learned counsel, held that the defendants were entitled to be indemnified by Messrs. Henley's Telegraph Works Company, at whose request the shares had been applied for, and entered judgment for the plaintiff company for £1,000 and costs.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *November* 27, 1891.

The Berliner Microphone Patent.—The recent telephone patent is still the topic of the hour. The patent records are at present inaccessible, as so many certified copies of the proceedings in this case have been ordered that documents are steadily in the hands of copyists. The Berliner patent has made all the greater sensation as there has been a widely spread, though erroneous opinion, that telephone apparatus would become practically free after the expiration of Bell's original patent dated 7th March, 1876. The establishment of the microphone claims has been a rude awakening to those who had hoped for any such termination of the telephone monopoly. There will undoubtedly be vigorous competition set on foot by 1894, when the second Bell patent runs out; indeed, there are rumours even now of organizations preparing to go into the telephone business at the earliest opportunity; but to all these the Berliner claim, whether substantiated or not, will be somewhat of an inconvenience, although it is generally admitted that it will be very difficult to hold the patent against the attacks that will be made on it.

A 125 H.P. Thomson-Houston Electric Locomotive.—The Thomson-Houston Electric Company has recently been building an electric locomotive of capacity sufficient for handling freight cars; it will be formally exhibited to an invited delegation of electricians to-morrow, but some details regarding the apparatus have already leaked out. The machine is to be used at Whitingsville, Mass., and is to be employed for the purpose of handling freight cars between the works of the Whiting Machine Company and the railroad, about two miles distant. The locomotive complete weighs about 21 tons, and is driven by a single motor of about 125 H.P. capacity, the wheel base is six feet four inches, and the motor drives directly a single pair of wheels three feet six inches in diameter; these are connected to the other pair by the connecting rods. The normal axle speed will be about 40 revolutions per minute, while the armature will make nearly 1,000. The speed reduction is accomplished by spur gearing running in oil. In the cab of the locomotive is placed the controlling mechanism with the other accessories necessary, the power to be supplied by an overhead wire, from which current will be taken by the trolleys as usual.

The Electric Railway Business.—The electric railway business in general is a little sluggish just now, owing to the lateness of the season, but construction is kept up all winter, and the principal companies are still busy turning out machines. These are now nearly all single-reduction with a few gearless, and a few of the old type for use on already established roads who are opposed to innovation. Single-reduction machines, however, have now acquired so good a reputation that they are usually ordered for regular equipments. Railway managers still look askance at gearless machines, and indeed it is quite possible that they may continue to do so if the single-reduction gear motors give as thorough satisfaction as they seem to be doing at present.

CORRESPONDENCE.

PLATINOID *v.* COPPER FOR D'ARSONVAL GALVANOMETERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of the 4th inst. Mr. C. W. S. Crawley refers to the question of whether d'Arsonval galvanometers should be wound with platinoid or copper, which had been raised by Prof. Ayrton in the discussion on Captain Sankey's Paper.

Although copper has important advantages where the instrument is only required to measure the *current* passing through it, its large temperature coefficient is a serious objection in cases where a *potential difference* is to be deter-

Digitized by Google

mined from the deflection of the galvanometer. The latter condition was the one under which Captain Sankey's instruments were used, and here platinoid might have been employed with advantage.

In the case of the 500-ohm instrument chosen by Mr. Crawley as an example, the difference of $\frac{1}{80}$th per cent. in the temperature coefficient may not seem large; but to estimate it at its true value it should be remembered that the temperature coefficient of the all-platinoid instrument is only about $\frac{1}{30}$th per cent., whilst that of the copper-platinoid combination is $\frac{1}{28}$th per cent. The temperature coefficient is therefore nearly double that of the simple platinoid galvanometer. Now, the disadvantage of nearly doubling a temperature coefficient is too well known to need further comment; in fact, it is a difference of the same order as that between platinoid and German silver.

But Mr. Crawley in his comparison has entirely neglected the resistance of the suspension of this coil, and, as this suspension is constructed of platinoid wire by well-known instrument makers, this resistance alone amounts to 10 ohms. Now this omission would lead to totally wrong conclusions if we were comparing the relative advantages of platinoid and copper-wound d'Arsonval galvanometers of somewhat low resistance, and, indeed, even in the case he refers to, the real sensibilities for P.D. are not in the proportion of 1 to 25, as stated by him, but as 20 + 10 to 500 + 10, that is as 1 to 17.

If, however, the current to be measured be such that 10 ohms be the right resistance to give to the coil when wound with platinoid, then if wound with the same number of turns of copper wire of the same gauge its resistance will be 0·4 ohm. Hence, since the total resistance between the galvanometer terminals, including the suspension, will be 10·4 ohms for the copper-wound coil and 20 ohms for the platinoid, the copper-wound instrument will not be even twice as sensitive as the platinoid one, and will have nearly twice the temperature coefficient.

For low-resistance d'Arsonval galvanometers it would be, be, however, a mistake to employ the same number of turns of wire of the same gauge, whether the wire were of copper or of platinoid. In fact, since there is this fixed resistance of about 10 ohms in the suspension itself, the coil should have 10 ohms resistance, so as to obtain maximum sensibility for potential difference measurement, whether wound with copper or platinoid. And if each coil have the same resistance there will be something like four times as many windings in the copper coil as in the platinoid. Hence, both for potential difference and for current measurement such a copper-wound instrument will be about four times as sensitive as the platinoid one, but it will have nearly 10 times as large a temperature coefficient.

The choice in this case, therefore, lies between a copper-wound instrument with sensibility 4, and a temperature coefficient $\frac{1}{5}$ per cent., and a platinoid-wound instrument with a sensibility 1, and a temperature coefficient $\frac{1}{30}$ per cent.

If sensibility for small potential difference is all important then the former is the better; whereas if constancy of sensibility for potential difference measurement at various temperatures is the chief desideratum, then the platinoid-wound instrument is undoubtedly superior.

But probably the best way of showing the superiority generally of platinoid-wound d'Arsonval galvanometers for potential difference measurements is by giving the following concrete example:—Let no alteration whatever be made in the platinoid sheet used at Thames Ditton to carry the main current, but let the 430-ohm copper coil of the d'Arsonval galvanometer used to measure the potential difference at the terminals of this sheet be replaced by a 10-ohm platinoid coil, the price of which would, of course, be less; then the deflection for a given current passing through the sheet will be increased 25 per cent., and the temperature coefficient reduced to $\frac{1}{18}$th of its value for the copper coil.

As I have already trespassed so much on your valuable space I will not go into further details, and the subject is fully dealt with in a forthcoming work on "Galvanometers" by the present writer.—I am, &c.,

T. Mather.

Central Institution, Exhibition-road.

THE THEORY OF THE WIMSHURST MACHINE.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: As M. Pellissier appears to me to have raised several new points in his last letter, I should be glad if you will permit me to say a few words in reply; after which I shall be satisfied to leave it to you and your readers to decide on the merits of the controversy, and thereby remove M. Pellissier's apprehension that it may trench on the boundaries of eternity.

Arguing from the quotation from Prof. Thompson's theory we are, according to M. Pellissier, left to choose one of two alternatives, namely, that Prof. Thompson either (i.) starts with the symmetrical distribution on one plate which I have assumed, or (ii.) assumes that the positive electrification of B_5 is produced by the influence of A_1. M. Pellissier maintains that the second alternative is an impossible one, because the neutralizing rod is to earth at the middle. But I think he forgets that there is usually no metallic connection between the middle of the neutralizing rod and the earth, but a support of well-seasoned wood. This is a sufficiently good insulator to produce a discharge of positive electricity on the carrier B_5. This, I think, with all deference to M. Pellissier's different interpretation, is Prof. Thompson's view; for he says, "As each carrier comes up to be touched by the neutralizing brush there will be a rush of electricity *between the two ends of that diagonal conductor*, where similar actions, but of opposite sign, are taking place."

M. Pellissier's theory of lateral action would thus be unnecessary to explain the creation of a charge on the second half of each plate. It also appears to me, after reading his amended exposition of his theory in *La Lumière Electrique*, October 10th, that the theory of lateral action is insufficient; and for the following reason. When a carrier in contact with a brush receives, say, a negative charge by the lateral action of a positive carrier that follows, it will tend to prevent this follower when in contact with the brush from receiving an equal negative charge. The result will be that by lateral action the effect of the second half of the plate will be nearly equivalent to what it would be if half its carriers were removed. This, we know, except with machines having an unnecessarily large number of carriers, would prevent increase of the charge.

In his article in *La Lumière Electrique* and in his last letter M. Pellissier abandons the attempt to explain the auto-excitation of the Wimshurst machine, and contents himself with explaining the process by which the machine is excited by the application of an external electrified body. His reason for considering this a sufficient theory is:—"Auto-excitation is not an essential part of the action of the machine, since the machine requires in certain cases to be excited." Since these machines are always made self-exciting, surely this is a *non sequitur*.

Finally, I was surprised to note that M. Pellissier claims to be the originator of the theory of the growth of the charges on which part of the theory this discussion at least has shown that he and I are in perfect agreement. I was surprised to note this, because it is the theory which I have always held on this question, and is identical with the theory which I venture to say anyone, on full consideration of all the circumstances, will find given in my book. M. Pellissier has put a different interpretation on my explanation of this theory; but the words he underlines do not necessarily mean that "fresh charges are added to the old ones as in the ordinary multipliers." Even on the true theory of growth, claimed by M. Pellissier, and expounded with the lucidity characteristic of his countrymen, I maintain that it is correct to say that, *owing to the motion of this latter disc, the charges originally upon it will be increased by its action*; for throughout my explanation I have considered the charges on the two halves of the discs as stationary in space while the discs with their carriers were rotating, and therefore not as charges attached to any particular carrier. This method I think very much simplifies the theory; and these stationary, positive, and negative charges on opposite sides of the neutralizing rods *do* increase, owing to the motion of the discs according to the compound interest law as I have stated in the next sentence.—I am, &c.,

J. Gray.

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.]

TENDERS INVITED.—The Aston Manor Local Board invite tenders for the complete electric light installation of the public baths. Further particulars may be obtained from Mr. W. A. Davies, A.M.I.C.E., engineer to the Board, Public Offices, Aston Manor, and tenders are to be sent to the Chairman of the Baths Committee by the 21st inst.

CHRISTIANIA (NORWAY).—We announced in our last issue that Messrs. Schuckert and Co. had obtained the contract for lighting the town of Christiania. The central station, which is intended to work at the commencement with 1,200 minimum to 1,600 maximum horse-power, and with a large plant of accumulators, is to be completed by the autumn of 1892, and is to cost, including buildings, &c., about £60,000.

CRYSTAL PALACE EXHIBITION.—We learn that one of the attractions at the forthcoming Electrical Exhibition at the Crystal Palace will be a telephone-room fitted by the National Telephone Company, in which music from the provincial and metropolitan theatres will be heard by telephone. The National Company will also establish inter-communication in the Palace between the various stalls, and their own exhibit will form an interesting feature of the Exhibition. Arrangements are being made for establishing communication between the Exhibition at the Palace and the metropolitan exchanges.

THE ST. PETERSBURG ELECTRICAL EXHIBITION.—The *St. Petersburg News* states that the number of French exhibitors at the St. Petersburg Exhibition increases every day, and it is even now possible to predict a very full exhibit from French manufacturers of electrical plant and apparatus. The French electrical engineers are, continues the journal, exhibiting many novel electrical inventions and improvements which up till now the Russian public were unacquainted with. No mention is made of any prominent British exhibit.

MESSRS. EWART AND SON.—This firm have recently added to their old-established business at Euston-road, N.W., an electrical engineering department, and notify us that they have several important contracts on hand. Messrs. Ewart and Son also supply electrical fittings and contract for house wiring, &c.

THE SMITHFIELD CLUB CATTLE SHOW.—The ninety-fourth annual show of this Club is being held this week, and closes to-day (Friday). The usual exhibits of engines, &c., were on view, but little or nothing of electrical interest was to be seen. Messrs. Crossley Bros. (Limited) had on view one of their B type of electric light engines, fitted with all the latest improvements. Mr. E. S. Hindley showed a number of his well-known portable and semi-fixed engines. The Priestman oil engine and the Trent gas engine occupy the usual prominent positions; but as one of the rules of the Smithfield Club prohibit the exhibition of working machinery, little interest was taken in the exhibits. Messrs. Robey and Co., Messrs. Ransomes, Sims and Jefferies, Messrs. Marshall, Sons and Co., Messrs. Francis Morton and Co., and Messrs. W. H. Willcox and Co. each had on view some fine examples of their special manufactures.

ELECTRICAL SIGNS.—Messrs. G. Shearod and Co., of 2, Praed-street, W., notify us that they are prepared to submit sketches and designs for stands, signs, show-cards, &c., and for the fixing of same, for the Crystal Palace Exhibition. This firm were entrusted by the Canadian Commission of the Colonial and Indian Exhibition with the sign work required for their extensive exhibit.

MESSRS. J. K. FAHIE AND SON.—This firm notify us that they are installing the electric light at the residence of Mr. J. J. Murphy, the well-known Irish brewer. The installation is for 100 incandescent lamps. The plant consists of a Robey engine and a 6-unit Elwell-Parker dynamo. Accumulators will also be used.

MESSRS. RALPH HEATON AND SONS, THE MINT, BIRMINGHAM.—This firm inform us that they have appointed Messrs. Edward Le Bass and Co., of 49, Lime-street, E.C., as agents for their London home and export trades. They call special attention to their seamless copper tubes, manufactured under a new process, and a special high conductivity copper wire for electric light and telephone work.

MESSRS. BAGSHAWE BROTHERS AND CO.—This firm send us particulars of their manufacture of "Standard" wood separable or split pulleys, which are known as the "Dodge" pulleys. Amongst the advantages claimed for these pulleys are their lightness and excellent belt surface. The list shows at a glance the cost of any diameter of pulley and width of face. The patent bushing system of pulleys associated with these pulleys consists of a simple method of bushing pulleys that may be utilised on shafts of various sizes.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

October 23, 1891.

18,199. A. MARR. Manchester. Improvements in and connected with telephone exchange switches.

18,207. A. T. COLLIER. Manchester. Improvements in electric telephones

18,251. SIEMENS BROS. AND CO., LTD., and F. G. BAILY. London. Improvements in electricity meters.

18,256. A. S. FORD. London. An improved process for the electro-deposition of metal upon the surface of glass, porcelain, china, earthenware, and other materials. (H. Pother, France).

October 24, 1891.

18,272. J. CHADWICK. Manchester. Improvements in electric belts for body wear.

18,285. A. BURTON. Birmingham. Improvements in electric switches.

18,290. A. P. LUNDBERG. London. Improvements in switches for electric lighting.

18,304. H. HIRST. London. An improved device for trueing the commutators of dynamo-electric machines.

18,318. G. L. HALL. London. An improved electrical safety-switch.

18,348. T. PARKER, J. H. WOODWARD, and E. S. G. REES. London. Improvements in and connected with the distribution of electricity.

October 26, 1891.

18,421. J. M. ORMES. London. A new or improved electric lighting system. (S. L. Trippe, United States).

October 27, 1891.

18,423. SIR C. S. FORBES (Baronet). London. An improved telephone combination.

18,431. M. WADDELL, J. B. ENTZ, and W. A. PHILLIPS. Manchester. Improvements in secondary batteries.

18,432. S. J. ROLLASON. London. A portable electric illuminating advertisement.

18,436. SIR W. THOMSON. Glasgow. Improved apparatus for measuring and recording electric currents.

18,451. A. R. BENNETT. London. Improvements in telephonic switching apparatus.

18,477. O. SCHLESINGER. London. A depolarizing liquid for galvanic batteries.

18,505. W. B. CLEVELAND. London. A new or improved electric circuit controller or appliance.

18,522. W. P. THOMPSON. Liverpool. Improved method of and apparatus for welding or working metals electrically. (C. L. Coffin, United States).

18,524. W. P. THOMPSON. Liverpool. Improvements in insulators or insulating supports for electric conductors. (R. Hewitt and F. L. Pope, United States.)

October 28, 1891.

18,534. A. MARR. Manchester. Improvements in electric telephonic instruments.

18,551. C. J. HALL. London. Improvements in or relating to electrical terminals.

18,595. H. T. HARRISON and G. W. BUDD. London. Improvements in electric meters.

18,597. E. ANDREOLI. London. Improvements in electrolysis.

October 29, 1891.

18,626. J. C. RICHARDSON. London. Improvements in the construction of electrodes, for use in the electrolysis of solutions

18,627. J. C. RICHARDSON. London. Improvements relating to electrodes to be used in the electrolysis of solutions.

18,629. W. T. GARNETT. Bradford. Improvements in electric-dynamos and motors.

18,641. B. F. KELLY. Birmingham. Improvements in electrical apparatus

18,646. H. CHITTY. Chiswick. Improvements in electric motors and dynamo machines.

18,650. The ELECTRICAL ACCESSORIES COMPANY, LIMITED. London. Improvements in electrical switches.

18,653. N. SHAGOURI and J. H. HALE. Bristol. Improvements in means, electrically operated, for retarding and arresting the motion of trains, applicable also to tramcars.

October 30, 1891.

18,714. F. E. GRIPPER and S. COYLE. London. Improvements in the regulation of gas and oil engines for electric lighting purposes.

18,716. A. WRIGHT. Brighton. Improvements in electricity meters.

18,723. C. S. SNELL and WOODHOUSE AND RAWSON UNITED, LIMITED. London. Improvements relating to resistance frames and the like used for electrical purposes.

18,726. A. MARR and A. T. COLLIER. Manchester. Improvements in the cores of electric coils.

18,733. A. Marr and A. T. Collier. Manchester. Improvements in and connected with electric telephonic apparatus.

18,771. H. Pieper, Fils. London. Improvements in electric railway brakes.

18,775. Siemens Bros. and Company, Limited, G. S. Grimston and E. Perrett. London. Improvements in electric bell indicators.

October 31, 1891.

18,784. J. Swinburne and W. Fox-Bourne. Teddington. Improvements in electrical measuring instruments, dynamo-electric machines, registering instruments, and transformer switches.

18,801. T. H. Smith. Leeds. Improvements in electric arc lamps.

18,831. G. Cohen. Manchester. Improvements in magnetic electric hair-pins, curling pins, and similar articles.

18,834. A. Howison and W. J. Nelson. Manchester. A novel application of electricity to domestic purposes.

18,837. Siemens Bros. and Company, Limited. London. Improved means for supporting overhead electrical conductors round curves for electric railways or tramways. (Siemens and Halske, Germany).

November 2, 1891.

18,854. F. T. Schmidt. Bradford. Improvements in the construction of electrically controlled arc lamps.

18,855. W. S. Freeman. Otford. Improvements in dynamos and electric motors.

18,857. E. H. P. Humphreys. London. Improvements in meters for measuring electricity.

18,890. Siemens Bros. and Co. (Limited). London. Improvements in rotary phase current motors and dynamos.

18,897. R. Wood. London. Improvements in methods of apparatus for regulating the supply of electricity used for lighting, motive power or other purposes.

18,898. W. F. Taylor and G. J. Philpott. London. Improved insulating and protecting devices for concentric electric mains.

18,899. W. F. Taylor and G. J. Philpott. London. Improvements in electric meters.

18,902. G. F. Redfern. London. Improvements in the manufacture of tubular conduits for electric conductors. (S. Bergmann, Germany.)

18,905. J. O. y. Espinosa. London. Improvements in electric railway signals, part of which are applicable to other signalling or alarm purposes.

November 3, 1891.

18,916. R. D. Nuttall. Birmingham. Trollies for electric cars.

18,928. E. R. Dale. London. Improvements in the application of electricity to various useful purposes.

18,931. J. Pullmann and H. Lane. London. Improvements in apparatus and process for obtaining aluminium or other metals by means of electricity.

18,938. L. Langhans. London. Process for producing filaments for incandescent lamps.

18,974. T. Parker. London. Improvements in electrical furnaces for the manufacture of phosphorus or other matters capable of being volatilized by heat.

18,906. T. Parker and E. S. G. Rees. London. Improvements in arc electric lamps.

November 4, 1891.

19,020. A. R. Bennett. London. Improvements in telephonic switching apparatus.

19,047. J. Cerpaux. London. Improvements in and apparatus for reducing or condensing induction currents.

19,056. H. V. Weyde. London. Improvements in reflectors and appurtenances used in electric light photography.

19,071. R. Langhans. London. Improvements in the manufacture of wires for incandescent lamps, and in connecting the said wires to the filaments.

November 5, 1891.

19,134. F. Teague. London. Improvements in or relating to electric meters.

November 6, 1891.

19,162. A. M. Thompson and W. W. G. Webb. Chester. Electric meter.

19,176. E. A. Wahlström. London. Improvements in rotating magnetic fields, and in multiphase alternating currents.

19,190. E. W. Watling. London. A multiple terminal for electrical distribution.

19,198. A. G. New. London. Improvements in apparatus for placing electric lamps in circuit in any desired order or sequence.

19,211. F. Teague and E. F. Moy. London. Improvements in or relating to electric meters.

19,225. Siemens Bros. and Co. (Limited) and A. Schloemer. London. A polarised electrical indicator.

19,233. J. F. Munsie. London. Improvements in and relating to electric railways.

November 7, 1891.

19,314. H. H. Lake. London. Improvements in and relating to incandescent electric lamps. (La Société dite Electriciteits Maatschappij, System de Khotinsky, Germany.)

November 9, 1891.

19,339. R. J. H. Pippette, London. Facilitating the operations of switching usually carried on in telephone exchanges by means of an improved switching apparatus.

19,348. R. W. Brownhill, Birmingham. An attachment or means for electrical measuring, sale and delivery, or delivery with measurement only.

19,385. E. Francis, Nottingham. Electric lamps applied to bicycles, tricycles, and all velocipedes; also for carriages and any vehicle with or without apparatus to work the same.

November 10, 1891.

19,390. H. G. Read, Salford. Improvements in dynamo-electric machines, and apparatus appertaining thereto.

19,398. A. Hoster, London. Improvements in or relating to bases for electrical switches.

19,424. W. H Parry and J. Whitehead. Birmingham. Improvements in electric globe and shade holders.

19,450. T E. Marsh and Woodhouse and Rawson United (Limited). London. Improvements in electric apparatus.

19,458. W. P. Thompson. Liverpool. Improvements in electric accumulators or storage batteries. (N. H. Edgerton, United States.)

19,469. R. Grove and C. Lehr, Junior. London. Improved device for bringing the receiving instruments of telephones against the ears of the person speaking, and returning the same to their position of rest, as also for circuiting the telephone in and out.

19,495. J. J. Powers and R. Van Buren. London. Improvements in machines for making clay conduits for electrical and other purposes.

19,501. R. Woodley, J. Spear, and W. Harris. Hull. A process for solidifying steel, iron, or other material susceptible to magnetic influence by the application of electrical energy.

November 11, 1891.

19,503. A. A. Day. London. Improvements in apparatus for electric testing.

19504. F. Bryan. London. Improvements in holders for incandescent electric lamps.

19,546. W. Hartnell. Leeds. Improvements in alternating current dynamos.

19,551. A. R. Upward and A. G. Buttifant. London. Improvements in electrical means of advertising.

19,553. P. G. Lironi. London. Improvements in magneto-electric cut-outs, or safety apparatus.

19,554. P. G. Lironi. London. Improvements in electric switches.

19,617. M. Müthel. London. Improved exciting fluid for galvanic zinc carbon batteries.

19,625. A. Grundy. London. Improvements in ceiling roses and wall sockets for electric lighting.

19,630. G. G. M. Hardingham. London, Improvements in electric cables. (Messrs. Felten and Guilleaume, Germany).

19,635. H. Count Von Pückler. London. An improved electric apparatus for alluring and destroying insects.

November 13, 1891.

19,666. C. P. Shrewsbury. London. Improvement in and connected with the application and utilisation of electricity in the driving of machinery, locomotion, and like uses.

19,667. C. P. Shrewsbury. London. An improvement in lamps or apparatus connected with electric lighting.

19,691. J. C. Lawson. London. An improved device for ozonising air or gas by means of electricity.

19,704. J. C. Richardson. London. Improvements relating to the application of depolarisers in electrolysis.

19,716. J. Von Orlowsky. London. Improved polar fastening for galvanic elements.

19,744. E. W. Smith. London. Improvements in alternating-current machinery.

19,775. A. Brener. London. Improvements in diaphragms for electrolytic decomposing apparatus.

19,778. R. A. Dawbarn. London. Improvements in electric lighting apparatus.

November 16, 1891.

19,824. W. G. Potter and C. Midgeley. Nottingham. Electric spiral lamp for general lighting purposes, for railway carriages, tramcars, and cabs.

19,835. W. A. Crook and H. J. Payne. Barnes. Improvements in gravity control, as applied to electric measuring instruments.

19,854. J. Dickson and R. G. Shapcott. London. Improvements in dynamo brushes.

November 17, 1891.

19,895. J. Atkinson. London. Improvements in incandescent electrical lamps.

19,899. T. Weighill. Liverpool. Improvements in telephone closets and other structures where it is desirable that they should be practically sound proof.

19,900. W. P. Thompson. Liverpool. Improvements in or relating to welding or working metals electrically. (C. L. Coffin, United States.)

19,909. A. Marr. Manchester. Improvements in telephonic transmitters.

19,914. J. B. Barton. London. Improvements in or connected with electric arc lamps. (W. Jandus, United States.)

NEW COMPANIES, STATUTORY RETURNS, &c.

AUTOMATIC GAS-LAMP LIGHTER COMPANY (LIMITED).—This Company was registered on December 7, 1891, with a capital of £6,000, in £1 shares, by Church, Rendell, Todd and Co., 9, Bedford-row, W.C. The objects are to acquire the benefit of a certain existing invention, No. 19,417 of 1890, for "Improved apparatus for automatically lighting and extinguishing street and other gas lamps," and to carry on the business of mechanical, gas, or electrical engineers, machinists, brass and iron founders, &c.

D. W. FORBES AND CO. (LIMITED).—This Company was registered on December 1, 1891, with a capital of £25,000, in £5 shares, by S. H. Peddar, 4, Palmerston-buildings, Old Broad-street, E.C. The objects are: To acquire and carry on the Smithfield Engineering Works, Blackwall, London, and to carry on the business of engineers, coppersmiths, iron and tin plate workers, shipchandlers, millwrights, manufacturers of cranes, engines, motors, and machinery, bridge builders, boiler makers, electric engineers, and manufacturers of electric apparatus, machinery, plant, and appliances, &c.

J. MURGATROYD AND CO. (LIMITED).—This Company was registered on December 1, 1891, with a capital of £5,000, in £5 shares, by Jordan and Sons, 120, Chancery-lane, London, W.C. The objects are to acquire and carry on the business of engineer, coppersmith, brassfounder and finisher, carried on by James Murgatroyd at the Standard Works, Lymm, Cheshire. Registered without Articles of Association. Registered office: High-street, School Brow, Warrington, Lancashire.

"LIGHTNING" (LIMITED).—This Company was registered on December 2, 1891, with a capital of £3,000, in £1 shares, by Slaughter and May, 21, Great Winchester-street, E.C. The objects are to establish, print, and publish newspapers, magazines, books, plans, and drawings of every description.

LONDON AND BIRMINGHAM MANUFACTURING COMPANY (LIMITED).—This Company was registered on December 1, 1891, with a capital of £15,000, in £5 shares, by Roscoe and Hincks, 23. Christopher-street, Finsbury-square, E.C. The objects are to carry on the business of manufacturing and furnishing ironmongers, ironfounders, brassfounders, engineering tool makers, and electrical engineers, &c., carried on by W. F Reynolds and J. Burford. Registered office: 39, Upper Thames-street E C.

BICESTER ELECTRICITY SUPPLY COMPANY (LIMITED).—This Company, which was registered on November 2, 1891, with a capital of £5,000 in £5 shares, has its registered office situate at the Market Hill, Bicester in the county of Oxford.

ELECTRIC WELDING COMPANY (LIMITED).—The following was filed on December 2, 1891. In the High Court of Justice, Chancery Division, Mr. Justice Romer, for Mr. Justice Stirling, at Chambers, Monday, November 23, 1891. In the matter of the Companies' Act, 1862, and in the matter of the Electric Welding Company (Limited). Upon the application by originating summons, dated October 8, 1891, of Thorndike Nourse, of 2, Austin Friars, in the City of London, financial agent, and upon hearing the solicitors for the applicant, and for the above-named Company, and upon reading the affidavit of the said Thorndike Nourse, filed October 23, 1891, and the exhibit therein referred to, and the affidavit of Arthur John Davis, filed November 25, 1891, and by consent. It is ordered that the register of shareholders of the said Electric Welding Company (Limited) be rectified by removing therefrom the name of the said Thorndike Nourse as the holder of one founders' share and 49 ordinary shares in the said Company; and it is ordered that notice of this order be given to the Registrar of Joint-Stock Companies by leaving a copy thereof with him; and it is ordered that the said Electric Welding Company (Limited) pay to the said Thorndike Nourse the sum of £11. 17s. 8d., being his ascertained costs of this application. Messrs. Snell, Son and Greenup, 1 and 2, George-street, Mansion House, E.C., solicitors for Thorndike Nourse. Registered office of the above-named Company: 6, Great George street, Westminster, S.W.

GENERAL ELECTRIC COMPANY (LIMITED).—The annual return of the above-named Company, made up to November 30, 1891, was filed on the following day. The Company was registered on July 25, 1891, with a capital of £60,000, divided into 7,000 First Preference, 1,000 Second Preference, and 4,000 ordinary shares of £5 each; 11,325 out of the 12,000 shares have been taken up, and upon 6,325 the full amount has been called and paid. The 4,000 ordinary and the 1,000 Second Preference shares were issued as fully paid. Gustav Binswanger, the Managing Director, holds 2,250 First Preference, 1,000 Second Preference, and 2,000 ordinary shares. Ferdinand Heys, of 7, Lothbury, holds 750 First Preference and 500 ordinary shares. Benjamin Newgass and Otto H. Edinger, of 7, Lothbury, E.C., jointly hold 1,496 First Preference and 450 ordinary shares. Registered office: 71, Queen Victoria-street, E.C.

ISLE OF WIGHT ELECTRIC LIGHTING COMPANY (LIMITED).—The registered office of this Company, which was registered on November 12, 1891, with a capital of £1,000 in £1 shares, was filed on December 4, 1891, and is situate at 21, Lime-street, London, E.C.

CITY NOTES, &c.

CHILI TELEPHONE COMPANY (LIMITED).—The Stock Exchange Committee have ordered shares Nos. 1 to 40,000 of this Company to be quoted in the Official List.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts of this Company for the week ended December 6th amounted to £310; aggregate receipts for half-year to date, £16,753.

COMMERCIAL CABLE COMPANY.—This Company officially announce the payment on January 2, 1892, of the usual quarterly dividend at the rate of 7 per cent. per annum. It is further announced that the drawing of bonds to take place this month for repayment in January will again be at the maximum of £120,000. The outstanding bonds will thereby be reduced to £200,000.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of November show a decrease of £7, as compared with the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of November were £2,235, as compared with £2,722 in the corresponding period of last year, showing a decrease of £487.

GREAT NORTHERN TELEGRAPH COMPANY (LIMITED).—The traffic returns of this Company in November, 1891, were £22,400; January 1st to November 30th, £260,200; corresponding months, 1890, £256,400; 1889, £252,400.

RICHARD HORNSBY AND SONS.—THE ELECTRICAL EXHIBITION AT THE CRYSTAL PALACE.—At the ordinary general meeting of this Company held on Wednesday, the 9th inst., Mr. James Hornsby, the Chairman, in the course of his remarks, said: In our engineering department we have been nearly as busy as last year, having obtained some good orders for electric lighting engines, together with an increased demand for most of our other engines. In this connection I may mention that we are supplying the whole of the motive power for generating the electrical energy to be used at the forthcoming Electrical Exhibition at the Crystal Palace, the plant being actually purchased, and afterwards to be used by a local company for the electric lighting of the neighbouring district. I hope that our

Digitized by Google

shareholders and their friends who visit the Exhibition will take the opportunity of seeing the five large engines and boilers supplied by us, which are erected at Upper Sydenham, about a mile from the Palace. The report was adopted.

NATIONAL TELEPHONE COMPANY (LIMITED).—The Directors have resolved to declare an interim dividend for the six months ended October 31st last at the rate of 6 per cent. per annum (less income-tax) on the first and second preference shares, and at the rate of 5 per cent. per annum (less income-tax) on the ordinary shares of the Company. The transfer books will be closed from the 7th to the 18th inst., and the dividend warrants will be posted on the evening of the latter date.

ST. PANCRAS VESTRY.—This Vestry invite tenders for a loan of £60,000, for electric lighting works, on the security of the parish rates. Tenders are to be sent to Mr. T. E. Gibb, the vestry clerk, on or before Tuesday, December 15th.

CRICKET.—EASTERN EXILES *v.* AMBER.—A cricket match was played at Malta on the 2nd inst. between the members of the ship and shore staff of the Eastern Telegraph Company, resulting in a victory for the mariners by 54 runs. Scores:—

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 709.—Vol. XXVIII. FRIDAY, DECEMBER 18, 1891. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6.

NOTES.

At a recent meeting of the New York Electric Club a most intereresting Paper was read by Mr. E. Rosewater upon the Government telegraphs of Europe; and an unusually long editorial comment is made upon it in the *Electrical World* of New York for December 12. It is there pointed out that while the German telegraph system has been much lauded, the German Government railway system and the Government cigars and tobacco are not brilliant examples of State monopolies. Mr. Rosewater observes that with one-half of the world's telegraphic line mileage American companies handled only 60,000,000 telegrams in 1889 against 204,935,055 telegrams handled in European countries alone, while Great Britain, with less than one-third of the wire mileage of the United States, handled 63,403,399 messages that year. The author of the Paper thinks it worth mentioning that the chief operator in a Welsh office declared most emphatically that he was a Radical, and decidedly opposed to the present Conservative party in power, and that a number of the operators in his office were either Radicals or Liberals; but if the Postmaster, who has supreme control of the telegraph force, dared to dictate what ticket they should vote, or undertake to interfere in any way with their rights as citizens, they should soon have a Parliamentary inquiry, and the Postmaster would soon find himself dismissed in disgrace. Such a thing, he adds, as trying to delay a political message, or tamper with it, or divulge its contents, has never been heard of in France.

Shipping disasters along the British coasts are following one upon another in quick succession, and the lesson we have preached for years past on the necessity of electrical communication with outlying lightships, and between all lighthouses and lifeboat stations, has been tragically illustrated by the casualties of the last few weeks. The terrible story recounted in *The Times* on Tuesday is only one of many that might be told pointing the same moral, though it may be hoped that none have had to tell of such suffering and loss of life. Within sight of the Galloper lightship the "Enterkin" merchantman was driven on the North Galloper Sands and dashed to pieces, only one of the crew being rescued by a passing fishing smack many hours afterwards, the lightship having no means of giving information to the shore as to the locality of the wreck. Two other men were picked up by an Antwerp steamer; and these are all that survived out of a crew of 30. We can only echo the words of *The Times* on this humiliating incident, that these brave men may not have died in vain, and that at last the national duty may be recognised of providing not merely warning of darger but succour when warning is of no avail.

While the alternate-current system of electric lighting is supposed to be specially applicable for pioneering work, the advocates of low-pressure distribution seem to get the ear of Town Councils, who sometimes never examine any other methods or invite competition. A town councillor, writing to a local paper on the electric lighting of an important suburb of London, remarks that the Committee of the Town Council entertain an opinion of the wisdom, the ability, and the disinterestedness of the contractors, that is something beyond what ordinary mortals are entitled to, and that they look upon the consulting engineer as a heaven-born genius; and the two in conjunction produce an amalgam which they consider it ill-conditioned rashness, if not sacrilege, to criticise. Modestly intimating that his knowledge is embryonic, he concludes his letter with a confident statement that a cheap supply is possible. "It is easy enough of attainment, for the electric fluid itself costs nothing; it is only the energy that is necessary to send it to the point where it is to be used that makes the largest item of expense." This remark is more accurate than might be expected from any one who uses the expression "electric fluid." In the leading article of our present issue we have questioned whether this fluid exists; and a good authority stated in the witness-box last week that "volts cannot be bought." The town councillor is perfectly right in his contention that it is only the energy that costs the money, and, with a slight verbal modification, his conclusion is thoroughly scientific.

The following letter is a sample of a suggestion which turns up every few months. We hesitated at first as to whether it should be printed in full in our correspondence columns, since it was not marked "private," but decided that it would be a mistake to give advertisement to such a firm. Sometimes we are offered illustrated abstracts of new patents, but a regular cash payment of £1 a month is something novel. A very large number of inventions are patented by the inventors themselves, since the facilities for doing so have been so greatly increased. The principle that he who is his own lawyer has a fool for his client is well known; but patents are often applied for by inventors on another principle, namely, throw enough mud, and some of it will stick. Any one having an invention

Digitized by Google

which promises to be really valuable should take it to a regular patent agent, and the additional sum spent on the fees of the leading members of the profession are quite trifling compared with the expenses of bringing out an important invention. In the absence of a strong recommendation, an inventor had better go to some firm of patent agents a member of which is a Fellow of the Chartered Institute of Patent Agents. It is hardly necessary to say that the following letter comes from no such firm :—

TO THE EDITOR OF THE ELECTRICIAN.

"————" and Co., Patent Agents, —, Chancery-lane, London,
Telegraphic Address, "————," London. W.C., Dec. 15, 1891.

DEAR SIR : We take the liberty of asking if we could make arrangements with you for being Patent Editors to your paper. Our suggestion is that you should insert a short paragraph among the matter of your paper as follows :—"If any of our readers have an idea for an invention they may have full particulars about patents and inventions *free* from our Patent Editor. Send stamped envelope." You would receive all letters and open same, should you wish it, and we would send for them and forward required answers. We believe it would be very useful to your readers and beneficial to us, and we are willing to pay you £1 per month for such Patent Editorship. We are Patent Editors in this way to "————," "————," "————," "————," "————," "————," "————," "————," and shall be pleased to be the same to your paper. We enclose you our pamphlet on patents, in which you will see the various papers we have dealings with. Our Mr. ———— will be pleased to call upon you any time by appointment to more clearly explain this system of giving Patent information, which has been entirely inaugurated by us.—Yours faithfully, ———— and Co.

OUR Paris correspondent is able to announce this week that the new year will witness the birth of yet another electrical journal. *L'Industrie Electrique*, as our Paris contemporary is to be christened, will be under the ægis of M. HOSPITALIER, and we may therefore expect the admirable lucidity of style which characterised the old *Electricien* ; but the equally commendable conciseness and compactness of that organ will, we fear, be wanting. *L'Industrie Electrique* proposes, like a true nineteenth century production, to be *big*.

IN the same letter our Paris correspondent also states that M. HEILMANN has found several spirits as bold as himself to subscribe 300,000 francs towards the expense of a practical test of his electric locomotive. M. HEILMANN'S idea is to mount a triple expansion engine on wheels, which shall drive a dynamo supplying "polyphase" currents to appropriate motors placed direct on the axle. At the other end of the scale we have the announcement that the firm of BRÉGUET have just completed an "accumulator locomotive" for a railway company. It is difficult to say which scheme seems the more lacking in practicability.

THE manners and customs of Englishmen differ so widely from those of Frenchmen, especially during their hours of leisure, that the great success which has met the "theatrophone" in Paris cannot be accepted even approximately as an indication of the demand which may be made by Londoners for sixpenny or shilling snatches of operas. Should Mr. SZARVADY find that his very ingenious instrument is not sufficiently well patronised by the frivolous, we would suggest that he should turn his attention to the House of Commons, the Law Courts, or the London County Council. The automatic indicator in front of the instrument, instead of giving the name of the theatre, should show "Overhead Wires Bill—Hicks-Beach," or "Brush *v.* King Brown—Moulton," or "Municipal Electric Lighting—Burns."

Fire at the Khotinsky Glow-Lamp Factory.—On the 2nd inst. a fire occurred at the Khotinsky glow-lamp works at Glenhausen.

Cardiff.—The Lighting Committee have decided to defer the application for a Provisional Order permitting them to light the town by electricity.

Electric Lighting of Omnibuses in Berlin.—According to the *Elektrotechnische Rundschau*, the Berlin General Omnibus Company is about to try lighting their rolling stock by electricity.

Cable Repairs.—The Société Française des Télégraphes Sous-Marins inform us that their cable between Cayenne and Vizeu, which has been interrupted since October 22nd, was repaired on December 1st.

St. Pancras Vestry.—The Prudential Assurance Company has offered to advance £60,000 at 3½ per cent. interest for 42 years to the St. Pancras Vestry in connection with its electric lighting scheme.

Domestic Telephones.—At the Adelphi Hotel, Liverpool, which has lately been renovated, a complete system of telephonic inter-communication between one visitor and another, and between all visitors and the hotel staff, has been installed.

Plymouth.—At a recent meeting of the County Council it was decided to ascertain the desirability or otherwise of obtaining powers for lighting the borough by electricity, and also whether water power could be made available for generating electricity.

The Electrical Utilisation of Water-Power at Marburg.—A project is on foot, suggested by the success of the Lauffen-Frankfort experiment, for conveying 600 H.P. by electricity from Marburg to St. Lorenzen, a distance of 18 miles. A head of water, over 200ft., is available at the former place.

Bradford.—At the monthly meeting of the Town Council, on Tuesday last, the Gas and Electricity Supply Committee recommended the Council to direct that all necessary steps shall be taken for extending the area so as to include the district of Allerton. The recommendation was agreed to.

Mutual Telephone Company.—There are now over 830 subscribers to the Mutual Telephone Company in Manchester. The system is being extended by the erection of trunk lines between Manchester, Farnworth, and Bolton. It is expected that these will be completed by the end of the present month.

Sheffield.—The General Purposes and Parks Committee of the Town Council at their last meeting resolved to recommend the Council to adopt electric light for the Council Chamber, and to accept the tender of the Sheffield Telephone Exchange and Electric Light Company to fix a sufficient number of lamps to light it efficiently.

Mica.—A mica discovery is now reported from Natal. The extent of the bed has still to be proved, but it has been stripped for a length of 100ft. and to a depth of 30ft. The mica occurs in small pockets, and ranges in size from about 8in. in length by 4in. in breadth on the surface. At a depth of 27ft. the mica is very short and the cleavage very imperfect.

Vienna Street Traffic.—In view of the agitation for the construction of an electric "Metropolitan" railway, it may be interesting to note that according to Herr Prasch, Inspector of Telegraphs, the internal traffic of Vienna is relatively only half as intense as that of London, a fact, which is, he thinks, largely attributable to the lack of rapid transit.

Electricity in Calico Printing.—La Société Industrielle de Mulhouse are offering, amongst others, a silver medal for the application, in any form, of electricity to calico printing. Full

Digitized by Google

particulars regarding the competition can be obtained by applying to the Society, and all applications for the awards should be sent in on or before February 15, 1892.

The Telephone in Costa Rica.—A Belgian firm has been granted a concession for erecting telephone exchanges in the Republic of Costa Rica, to be connected together by trunk wires. Some of the existing telegraph lines will be employed as interurban telephone wires by the adoption of the Van Ryssel-berghe system. Dejongh transmitters and Bell receivers will be employed.

Electric Lighting on Railways.—The Directors of the San Paulo (Brazilian) Railway Company, in their report just issued, announce that plant for the electric lighting of the new goods yard at Pary has been sent out, and that they have ordered the necessary plant for lighting the Serra inclines by electricity, so that they may be worked by night, and thus increase the capacity of the line.

Weston-super-Mare.—At the last monthly meeting of the Town Commissioners, the taxed costs in connection with the Weston-super-Mare Electric Provisional Order, 1891, were reported to be £370. 13s. 11d. A sub-committee was authorised to visit such towns where electric light had been adopted for public and private purposes, and to obtain all information on the subject.

The Sims-Edison Torpedo.—A trial of the Sims-Edison dirigible torpedo was made on Tuesday on the Tyne at Newcastle before Sir William G. Armstrong, Mitchell, and Co. This trial was made to demonstrate the practicability of launching a dirigible torpedo from a ship in motion, and notwithstanding very bad weather, rain and fog, it seemed eminently satisfactory. An exhibition will shortly be given before the Lords of the Admiralty at Stokes Bay.

The Electrical Standardising, Testing, and Training Institution.—The library of this Institution was the scene of a very interesting ceremony on Monday last, when the First Year Students took the opportunity of presenting Mr. H. Doyer, the Demonstrator, who is leaving at the end of the year, with complete sets of Sir William Siemens' and Joseph Henry's works, as a mark of their respect for him, and, at the same time, of expressing their good wishes for his future.

The Berlin-Königsberg Trunk Wire.—According to the *Elektrotechnische Zeitschrift* the project for connecting these two towns by telephone will be carried out next spring. The length of the line from Berlin to Dantzig will be about 260 miles, and from Dantzig to Königsberg about 100 miles, making a total of 360 miles. The longest line in Germany at present is that from Berlin to Breslau, 220 miles, and after this comes the Berlin-Hamburg line, with a length of 170 miles.

Singapore.—The question of lighting Singapore by the electric light is, we understand, receiving attention. Gas is very expensive, and the introduction of the electric light has to meet with the opposition of the Municipal authorities, many of whom are interested in the gas companies. Owing to the large sums of money required for what is known as "military contribution," this colony's treasury is considerably drained, but we understand the prospects of introducing the electric light are favourable.

The City and Guilds of London Institute.—The prizes and certificates won in the City and Guilds of London Institute for the Advancement of Technical Education were distributed in Salters' Hall, St. Swithin's-lane, on Monday evening. The Lord Mayor presided, and among those present were Sir George R. Bruce (past president of the Society of Civil Engineers), Sir Frederick Abel, Sir Owen Roberts, Sir Philip Magnus, Sir Sydney Waterlow, Mr. H. C. Saunders, Q.C., Mr. Daniel Watney, Prof. W. C. Unwin, and Prof. Silvanus Thompson.

Iron Rail Telegraph Posts.—The Great Indian Peninsula, says the *Engineer*, is utilising old rails as telegraph posts, and they are cheap and durable, as well as strong and inflexible. An extra piece of rail is bolted to the rail at its lower extremity, generally from 4ft. to 6ft. long for an ordinary telegraph post. Sometimes two pieces are necessary for specially long poles. This end is then buried in the ground, and the pole is ready for its fixings. The cost is about from eight to ten rupees each as against from at least twenty to thirty rupees for wooden posts, and even more for galvanised iron uprights.

Old Students' Association.—On Wednesday last a meeting of this Association was held at Finsbury Technical College, when Mr. Rollo Appleyard read a Paper on "The Measurement of the Resistance of Conductors containing Disturbing E.M.F." He gave results of a number of experiments, when the tangent galvanometer method of measuring earth-plate resistance was used, and showed that this method often leads to erroneous results. On the other hand, by using a Wheatstone bridge, furnished with a special key (keeping *all* the circuits open until it is depressed), he was enabled to obtain results which did not greatly differ on various dates.

Magnetic Properties of Liquid Oxygen.—Prof. Dewar made last week a highly interesting communication to the Royal Society. He sought to determine what effect a temperature of − 180°C. would have upon the behaviour of liquid oxygen in the magnetic field. Having previously ascertained that liquid oxygen does not moisten or adhere to rock crystal, and consequently maintains in contact with that substance a perfect spheroidal condition, he poured the liquefied gas into a shallow saucer of rock crystal, and placed it between the poles of the Faraday electro-magnet. On the magnet being excited, the whole mass of liquid adhered to the poles until dissipated.

Electric Lighting of the County Council's Offices.—At the last meeting of the London County Council the Committee reported that they had authorised the connection of the installation with the mains of two supply companies being put in hand at once; and that they had accepted the estimate of the London Electric Supply Corporation for low-tension mains from their Red Lion Yard station; and the estimate of Messrs. Mather and Platt for the Electric Supply Corporation. The Committee asked that the course taken should be approved, which was agreed to. The tenders for the installation work were opened by the Council, and are given in our Trade Notes column.

The Trolley Wire.—"The latest trolley wire sensation," says the *Electrical World*, "hails from Pittsburgh, and furnishes a beautiful illustration of the singularly true remark made not long since that to those working around electric wires gravity is far more dangerous than the current. A steam fitter at work in a railway power station undertook to drive a nail and struck a trolley wire; the shock threw him from the ladder on which he was perched, and the fall produced a fracture at the base of the skull, from which he soon died. To this statement of facts the reporter with the agile imagination blandly added, 'it is supposed, however, that he was dead before he reached the ground.'"

The Specification of Insulated Conductors.—A Correction.—On p. 146 of our last issue the formula given by Mr. Preece for the *specific insulation* (σ) of any insulating material should read as follows:—

$$\sigma = \frac{R' l 2\pi}{\log_\epsilon D/d},$$

where R′ is the resistance in C.G.S. units of the dielectric of a cable whose length is l cms., and whose insulating sheathing has inner and outer diameter of d and D respectively (D and d being in any units). In the same manner R′ must be substituted for ρ in Mr. Kempe's simple approximate formula on p. 147, which thus becomes $\sigma = R' l \times \frac{d+t}{t}$.

Taunton.—At a recent meeting of the Town Council, the Watch, Lighting, and General Purposes Committee advised that negotiations be entered into with the Gas and Electric Lighting Companies for the acquisition of their undertakings. Alderman Van Trump, in moving the adoption of the report, said there was no doubt there would be some difference of opinion on the matter, as was the case when the town purchased the waterworks. The town was now deriving a handsome profit from the waterworks property, and he ventured to think, if the terms were anything like favourable, that the gasworks would also be a useful source of income, and the electric lighting would be no drag on them. The report was then adopted in full.

Long-Distance Telephone Lines.—At present, says the *Chemical Trade Journal*, the American Bell Telephone Company of Boston has under way 50 long-distance telephone lines from Chicago to New York. Each of these lines takes two wires, making 100 lines of single wire, and as the distance from New York to Chicago is about 980 miles, the length of wire used in connecting these two points would be 98,000 miles. The size of the copper wire used in the construction of the long-distance telephone weighs 174lb. to the mile, making the total weight of the copper turned into wire for this one undertaking 17,052,000lb., or 8,526 tons, or 3,000,000lb. more than the total production of the Tamarack for the last year, or within about 1,800,000lb. of the combined output of the Quincy, Osceola, and Franklin; or, omitting the Calumet and Hecla, Tamarack, and Quincy, more copper than the remaining combined Lake Superior copper mines produced in 1890.

The Telegraph Line to Gilgit (Kashmir).—The problem of connecting Srinagar with Gilgit by telegraph is (says the *Indian Engineer*) one which is likely to tax to the full the ingenuity and scientific knowledge of Mr. Brooke's officers. To show the difficulties likely to be experienced, we have only to refer to the last report of the Telegraph Department. It is therein stated that in December and January exceptionally heavy snow caused long interruptions between Murree and Kashmir, Goragali and Rawalpindi, respectively, and also between Bakloh and Dalhousie. With regard to that between Murree and Kashmir, "the snow was so deep that the line was completely buried in places, and although troops were employed to assist in the work of clearing, the task proved too severe." If casualties of this kind occur in the comparatively low hills beyond Murree, it may readily be imagined how hard will be the task of keeping open communication over the snowy ranges between Srinagar and Gilgit.

Telephonic Fire Alarms.—At a recent meeting of the Leeds Corporation Fire Brigade Committee it was suggested that the extensive means of telephonic communication now existing in the borough might be utilised much more usefully than were the street fire alarms by which the brigade were frequently summoned to fires. These street-side apparatus were often subject to misuse. It was thought that ten or a dozen residents or firms might be found upon whose premises were telephones, with persons in charge thereof, who would permit indicators to be placed in prominent positions outside their houses or works, stating that the telephones within were available for any of the purposes already alluded to. In the course of the discussion of the subject it transpired that a number of renters of telephones had been approached, and that they had responded most favourably. The meeting was generally of the opinion that the utilisation of the present telephonic system would be very much cheaper and more effective than any possible development of street alarms.

Indian Telegraphs.—The Administration Report of the Indian Telegraph Department shows that during the last financial year the net additions to the system were 1,791 miles of line, 7,373 miles of wire, and 21 miles of cable. One hundred and sixty-eight new offices have been opened during the year, bringing the number up to 3,103. The accounts show a profit equal to 4·26 per cent. on the capital outlay. During the year some excellent work was done by the department in laying field telegraph lines. The Sikkim line was maintained, as also that in the Chin country. A new line in Assam, a section of the Chin Lushai country, was laid from Jhalnacherra to Fort Aijal, a distance of 59 miles, through a most difficult and unhealthy country. The other two sections of the line through Lushai, from Dimagiri to Fort Tregear and from Pokokko to Haka, were strengthened. The working parties suffered severely from sickness. One hundred and eighty-two miles of extra wire had to be laid to connect Hussan and Abbottabad with the bases of operations at Derband and Oghi, and from those points onwards 103 miles of field wire were laid, and 15 offices opened.

Telegraphic Extensions in Spain.—It is noticeable that while strenuous efforts are being made to induce the various heads of departments to reduce their estimates, with a view to an equilibrium in the Spanish Budget, the telegraph and telephone system is not to be allowed to suffer. According to estimates just drawn up by the Minister of the Interior, we find that it is proposed to create 357 new telegraph stations, and to establish four direct wires, one from Valcarlos to Cadiz, to join with the African cable; another from Barcelona to Bilbao, to join with the English cable; another from Irun to Fuentes de Oñoro, to establish direct communication between France and Portugal; and another between Madrid and Barcelona. A telephone line is also to be established, which will include Seville, Huelva, Cadiz, and Malaga. The Madrid paper, *El Imparcial*, of November 14th last, while expressing satisfaction at this decision, asks the Minister of the Interior and the Director of the Postal Department, why some means cannot be introduced for improving the existing service. "How is it," the paper asks, "that with a fall of a slight shower it becomes necessary to send despatches by post?"

The Indian Telegraph Service.—It is rather disheartening, says the Allahabad *Pioneer*, to be obliged to call attention once more to the case of the officers of the Indian Telegraph Service. But though the grievances of the department, after a prolonged agitation, received recognition at the hands of the Government not so long ago, it would appear that they have not by any means obtained redress. It may be remembered that in 1887 the Secretary of State sanctioned a reorganisation scheme, which was conceived in a liberal spirit, and was intended to settle once for all the grievances under which the service was then labouring. The Government of India, while professing to give effect to this reorganisation scheme, substituted one of their own, which entirely nullified any benefits that were granted to the department by the Secretary of State. At the same time a needlessly vexatious rule was introduced prohibiting officiating promotions from grade to grade. This rule presses very heavily on the department. For example, four senior officers are at present on long furlough, two of whom retire at the expiration of their leave, yet their places cannot under this rule be filled temporarily by officers in the grades below them. The junior officers are thus forced to fill the senior appointments without receiving any extra remuneration for the increased duty and responsibility thrust upon them; and the State thereby effects a considerable saving at the expense of the department. The Viceroy has also been memorialised by officers of the department, but with no better success. The officers of the Telegraph Department now intend to memorialise the Secretary of State on the subject.

The Thunderstorms of 1888-89.—At the meeting of the Royal Meteorological Society on Wednesday, Mr. W. Marriott gave the result of the investigation undertaken by the Society into the thunderstorms of 1888 and 1889. The investigation was originally confined to the south-east of England, but, as this district was found to be too circumscribed, it became necessary to include the whole of England and Wales. In 1888 there were 113 days and in 1889 123 days on which thunderstorms occurred in some part of the country. The number of days with damage by lightning was 33 in 1888 and 38 in 1889; and there were 56 days in each year on which hail accompanied the thunderstorms. The tables of hourly frequency show that thunderstorms are most frequent between noon and 4 p.m., and least frequent between 1 a.m. and 7 a.m. Thunderstorms appear to travel at an average rate of about 18 miles per hour in ill-defined low barometric pressure systems, but at a higher rate in squally conditions. The author is of opinion that individual thunderstorms do not travel more than about 20 miles, and that they take the path of least resistance, and are consequently most frequent on flat and low ground. The author believes that the thunderstorm formations are small atmospheric whirls—in all respects like ordinary cyclones; and that the whirl may vary from one mile to ten miles or more in diameter. There are frequently several whirls near together, or following one another along the same track. The numerous oscillations in the barometric curve are evidently due to the passage of a succession of atmospheric whirls; and it appears that lightning strokes are most frequent when these oscillations are numerous.

ELECTROMAGNETIC THEORY.—XXI.

BY OLIVER HEAVISIDE.

(Continued from page 111.)

§ 107. Coming next to the products of vectors, it is to be noted at the beginning that the ordinary idea of a product in arithmetic and in scalar algebra does not apply to vectors, because they are not scalars. We cannot, therefore, say beforehand what the product of two vectors ought to be, or determine this question by any prior reasoning of a legitimate nature. We must examine in what way vectors enter into combination as products, and then introduce definitions and conventions of notation to give expression to the facts in the simplest and most convenient way. After this, the work is deductive.

By this examination we are led to recognise two distinct kinds of products of a pair of vectors, the scalar product and the vector product. It is with the former of these that we are now immediately concerned.

We *define* the scalar product of a pair of vectors **A** and **B**, whose tensors are A and B, and whose included angle is θ, to be the scalar AB cos θ, and we denote it by **AB**. Thus

$$\mathbf{AB} = \mathrm{AB}\cos\theta \quad . \quad . \quad . \quad . \quad . \quad (12)$$

defines the scalar product and its notation.

To see its full significance and how it works out, let us first apply (12) to the unit reference vectors, **i**, **j**, **k**, which are coperpendicular, by taking **A** and **B** to be one or other of them in turn. First multiplying each of **i**, **j**, **k** by itself, we get

$$\mathbf{i}^2 = 1, \quad \mathbf{j}^2 = 1, \quad \mathbf{k}^2 = 1, \quad . \quad . \quad . \quad . \quad (13)$$

with the convention borrowed from scalar algebra that **ii** is equivalently denoted by $\mathbf{i}^2$. This may be called the square of **i**. In each of the three cases (13) the vectors multiplied together are of unit length, and are parallel and concurrent, so that the scalar product, according to (12), is unity.

Similarly, the square of any unit vector is unity. And since $\mathbf{A} = \mathrm{A}\mathbf{A}_1$, the square of any vector is the same as the square of its tensor; or

$$\mathbf{A}^2 = \mathrm{A}^2. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (14)$$

Also, the scalar product of any two parallel vectors is the product of their tensors, for $\mathbf{AB} = \mathrm{AB}\,\mathbf{A}_1\mathbf{B}_1$, and $\mathbf{A}_1\mathbf{B}_1$ is now unity.

Next make scalar products of **i**, **j**, **k** in pairs. We get

$$\mathbf{ij} = 0, \quad \mathbf{jk} = 0, \quad \mathbf{ki} = 0. \quad . \quad . \quad . \quad . \quad (15)$$

That is, the scalar product of two perpendicular unit vectors is zero. The same is, of course, true of any two perpendicular vectors. Thus the equation $\mathbf{AB} = 0$ means that **A** is perpendicular to **B**; unless, indeed, one or other of them is zero.

We have also

$$\mathbf{A}_1\mathbf{B}_1 = \cos\theta, \quad . \quad . \quad . \quad . \quad . \quad (16)$$

by dividing (12) by AB; or, the scalar product of any two unit vectors in the cosine of the included angle. This is reckoned positively from concurrent coincidence, so that as θ goes from 0 to 2π, $\mathbf{A}_1\mathbf{B}_1$ goes from 1 through 0 to − 1, and then through 0 again to + 1.

There is, strictly, no occasion to introduce trigonometry. Or we might make the trigonometry be a simultaneously developed subject. It is, in fact, a branch of vectorial algebra, being scalar developments of parts thereof. We may employ the idea of perpendicular projection simply. Thus, we may say that the scalar product of a pair of unit vectors is the length of the projection of either upon the other; and that the scalar product of any vector **A** and a unit vector **i** is the projection of **A** upon the axis of **i**; and, comprehensively, that the scalar product **AB** of any two vectors **A** and **B** is the product of the tensor of either into the projection (perpendicularly) upon it of the other. It is the effective product, so to speak. In physical mathematics scalar products frequently have reference to energy, or activity, or connected quantities. Thus, if **F** be a force and **v** the velocity of its point of application, their scalar product **Fv** is the activity of the force; it is the product of the speed and the effective force. When the force and the velocity are perpendicular, the activity is *nil*, although the velocity may be changing—a fact which familiarity does not render less striking. When **F** and **v** are parallel (whether concurrent or not), **Fv** becomes the same as F*v*, in the common meaning of a product. A notation that harmonises in this way is obviously a convenient one.

Notice, also, that **AB** = **BA**, as in scalar algebra.

A frequently occurring operation is the surface integral of the normal component of a vector; for example, to express the amount of induction through a surface. Here the idea of a unit normal vector **N** is useful. The normal component of **B** is then **NB**, and the integral is Σ**NB**, the summation extending over the surface.

Similarly, to express the line-integral of the effective component of a vector along a line, we may let **T** be the unit element of curve; that is, the unit tangent; then **TE** is the tangential component of the vector **E**, and Σ**TE** is the integral; for example, the voltage between two points along the path to which the summation refers, if **E** be the electric force.

Since **ab** is a scalar, it behaves as a scalar, when considered as a whole. Thus, when multiplied by a scalar, *x*, the result, *x***ab** or **ab***x*, is scalar, being simply *x* times **ab**. When multiplied by a vector the result is a vector; thus, **c.ab** or **ab.c** means **ab** times the vector **c**. The dot here acts rather as a separator than as a sign of multiplication. Thus, to illustrate, **ca.b** means **ca** times the vector **b**; and, similarly, **a.bc** is **bc** times the vector **a**. But, instead of the dot, we may use brackets to indicate the same thing, thus **c.ab** may be written **c**(**ab**). This is, perhaps, preferable in initiatory work, but I think the dot plan is more generally useful.

We have an example of this combination of three vectors in the stress formulæ. Thus, the electric stress vector on the plane, whose unit normal is **N**, is expressed by

$$\mathbf{E.DN} - \mathbf{N}.\tfrac{1}{2}\mathbf{ED}$$

(equation (31), § 72); that is, the sum of two vectors, parallel to **E** the electric force and to **N** respectively, whose tensors are **EDN** and $-\frac{1}{2}$**ED** respectively, where **D** is the displacement. The interpretation as a tension along **E** combined with an equal lateral pressure, obtained by taking **N** parallel to and then perpendicular to **E** or **D**, has been already discussed.

§ 108. As all the preceding is involved in the definition of a scalar product, and is obvious enough, it may be regarded merely as illustrative. The reader might, in fact, say that he knew it all before in one form or another, trigonometrical or geometrical, and that he did not see any particular advantage in the way of stating it in the notation of scalar products. But we now come to a very striking and remarkable property of scalar products, which will go far to justify them as working utilities.

We know that in scalar algebra, when we have a product *xy*, we may express *x* by the sum of any number of other quantities, and similarly as regards *y*, and then obtain the complete product *xy* by adding together all the component products obtained by multiplying every element of *x* into every element of *y*; and that this process may be carried out in any order.

Now, in vector algebra, we know already that there is a partial similarity, viz., that we can decompose a vector **A** into the sum of any number of others, and similarly as regards **B**. The question now is whether the scalar product **AB** is the sum of all the scalar products made up out of the components of **A** paired with the components of **B**, taken in any order. For example, if

$$\mathbf{A} = \mathbf{a} + \mathbf{b},$$

and

$$\mathbf{B} = \mathbf{c} + \mathbf{d},$$

is

$$\left.\begin{aligned}\mathbf{AB} &= (\mathbf{a}+\mathbf{b})\,(\mathbf{c}+\mathbf{d}) \\ &= \mathbf{ac} + \mathbf{ad} + \mathbf{bc} + \mathbf{bd}\,?\end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (17)$$

The answer is Yes, and the process of manipulation is the same as in scalar algebra, that is, as if all the vectors were scalars. Moreover, this property admits of demonstration in a sufficiently simple manner as to enable one to see its truth.

Start with the vector **A**, and first split it up into

$$\mathbf{A} = \mathbf{a} + \mathbf{b} + \mathbf{c}, \quad . \quad . \quad . \quad . \quad (18)$$

two or three vector components being sufficient for illustration. Now project the vector **A** perpendicularly upon any axis, say

Digitized by Google

that of **i**. According to our definition of a scalar product, the projection is **Ai**. Now it requires no formal demonstration, but becomes evident as soon as the meaning of the proposition is correctly conceived, that the projection of **A** upon any axis is the same as the sum of the projections of its component vectors, **a**, **b**, **c**, on that axis. That is, the latter projections are either all positive or all negative, and fit together to make up the projection of **A**; or else some may be negative and others positive, when there is overlapping and cancelling, but still with the same result algebraically. This is expressed by

$$\mathbf{Ai} = (\mathbf{a}+\mathbf{b}+\mathbf{c})\mathbf{i} = \mathbf{ai}+\mathbf{bi}+\mathbf{ci}, \quad . \quad . \quad . \quad (19)$$

got by multiplying (18) by **i**.

If we now multiply (19) by any scalar B, so that $B\mathbf{i} = \mathbf{B}$, which is any vector, since **i** may have any direction, we obtain

$$\mathbf{AB} = (\mathbf{a}+\mathbf{b}+\mathbf{c})\mathbf{B} = \mathbf{aB}+\mathbf{bB}+\mathbf{cB}, \quad . \quad . \quad (20)$$

the same as if we multiply (18) by **B** direct.

Similarly, we may split up **B** into the sum of any number of other vectors, say,

$$\mathbf{B} = \mathbf{d}+\mathbf{e}+\mathbf{f} \quad . \quad . \quad . \quad . \quad . \quad . \quad (21)$$

If we substitute this in (20) we have

$$\mathbf{AB} = \mathbf{a}(\mathbf{d}+\mathbf{e}+\mathbf{f})+\mathbf{b}(\mathbf{d}+\mathbf{e}+\mathbf{f})+\mathbf{c}(\mathbf{d}+\mathbf{e}+\mathbf{f}).$$

Now make use of the same reasoning which established (19) and (20), applied to the bracketed vectors, and we establish the property fully, with the result

$$\mathbf{AB} = (\mathbf{a}+\mathbf{b}+\mathbf{c})(\mathbf{d}+\mathbf{e}+\mathbf{f})$$
$$= \mathbf{ad}+\mathbf{ae}+\mathbf{af}+\mathbf{bd}+\mathbf{be}+\mathbf{bf}+\mathbf{cd}+\mathbf{ce}+\mathbf{cf};$$

the expansion being done formally as in scalar algebra in every respect; since the various terms may be written in any order, and each may be reversed, thus, $\mathbf{ad} = \mathbf{da}$.

I have already remarked that a good deal of geometry may be done by the addition property alone. The range of application is greatly extended by the use of the scalar product and the fundamental property (17).

To obtain the Cartesian form of **AB**, put the vectors in terms of **i**, **j**, **k**; thus

$$\mathbf{AB} = (A_1\mathbf{i}+A_2\mathbf{j}+A_3\mathbf{k})(B_1\mathbf{i}+B_2\mathbf{j}+B_3\mathbf{k}). \quad . \quad (22)$$

Now effect the multiplications, remembering (13) and (15). The result is

$$\mathbf{AB} = A_1B_1+A_2B_2+A_3B_3 \quad . \quad . \quad . \quad . \quad (23)$$

For example, the activity of a force is the sum of the activities of its component forces in any three coperpendicular directions. Or, if **A** and **B** are unit vectors, we express the cosine of the angle between them in terms of the products of the direction cosines of the vectors, each product referring to one axis. In (23) we may, if we please, vectorise the six scalars on the right side.

Since the square of a vector is the square of its tensor, we may express the tensor at once in terms of the tensors and the cosines of the angles between a series of vectors into which the original vector is resolved. Thus, for two,

$$(\mathbf{A}+\mathbf{B})^2 = \mathbf{A}^2+2\mathbf{AB}+\mathbf{B}^2, \quad . \quad . \quad . \quad (24)$$
$$(\mathbf{A}-\mathbf{B})^2 = \mathbf{A}^2-2\mathbf{AB}+\mathbf{B}^2; \quad . \quad . \quad . \quad (25)$$

and similarly for three,

$$(\mathbf{A}+\mathbf{B}+\mathbf{C})^2 = \mathbf{A}^2+\mathbf{B}^2+\mathbf{C}^2+2\mathbf{AB}+2\mathbf{BC}+2\mathbf{CA} \quad (26)$$

Here (24) and (25) apply to a parallelogram, and (26) to a parallelepiped. In (24), (25), if **A** and **B** be the vector sides of a parallelogram, then (**A**+**B**) and (**A**−**B**) are the vector diagonals; so (24) gives the length of one diagonal and (25) that of the other.

Adding (24) and (25) we obtain

$$(\mathbf{A}+\mathbf{B})^2+(\mathbf{A}-\mathbf{B})^2 = 2(\mathbf{A}^2+\mathbf{B}^2), \quad . \quad . \quad (27)$$

expressing that the sum of the squares of the diagonals equals the sum of the squares of the four sides. Similarly, by subtraction

$$(\mathbf{A}+\mathbf{B})^2-(\mathbf{A}-\mathbf{B})^2 = 4\mathbf{AB} \quad . \quad . \quad . \quad (28)$$

expressing the difference of the squares of the diagonals as four times the scalar product of two vector sides.

Equation (27) also shows that the sum of the squares of the distances of the ends of any diameter of a sphere from a fixed point is constant. For if **A** is the vector from the fixed point to the sphere's centre, and **B** the vector from the centre to one end of the diameter, then **A**+**B** and **A**−**B** are the vectors from the fixed point to the ends of the diameter. Whence, by (27), the proposition.

There is an application of this in the kinetic theory of gases. For when two elastic spheres collide they keep the sum of their kinetic energies constant. If, then, their velocities before collision be **A**+**B** and **A**−**B**, their velocities after collision are indicated by vectors from the origin (in the velocity diagram) to the ends of some other diameter of the sphere described upon the line joining their original positions (in the velocity diagram) as diameter; which is actually the new diameter depending upon the circumstances of impact.

§ **109**. It is occasionally useful to employ the reciprocal of a vector in elementary vector algebra. We define the reciprocal of a vector **a** to be a vector having the same direction as **a**, and whose tensor is the reciprocal of that of **a**. We may denote the reciprocal of **a** by $\mathbf{a}^{-1}$ or $1/\mathbf{a}$. Thus as $\mathbf{a} = a\mathbf{a}_1$, we have

$$\mathbf{a}^{-1} = \frac{1}{\mathbf{a}} = \frac{1}{a\mathbf{a}_1} = \frac{\mathbf{a}_1}{a} \quad . \quad . \quad . \quad . \quad . \quad . \quad (29)$$

Any unit vector is, therefore, its own reciprocal.

The reciprocal of a vector, being a vector, makes scalar products with other vectors. Thus $\mathbf{ab}^{-1}$ or $\mathbf{a}\,\mathbf{b}$ means the scalar product of **a** and $\mathbf{b}^{-1}$, and we therefore have

$$\frac{\mathbf{a}}{\mathbf{b}} = \mathbf{ab}^{-1} = \frac{a\mathbf{a}_1}{b\mathbf{b}_1} = \frac{a}{b}\mathbf{a}_1\mathbf{b}_1 = \frac{\mathbf{ab}}{b^2} \quad . \quad . \quad . \quad (30)$$

The tensor of $\mathbf{a}\,\mathbf{b}$ is $(a\,b)\cos\theta$, where θ is the angle between **a** and **b**, or between their reciprocals, or between either and the reciprocal of the other.

So $\mathbf{a}\,\mathbf{a}$ or $\mathbf{aa}^{-1}$ or $\mathbf{a}^{-1}\mathbf{a}$ equals unity.

In using reciprocals the defined meaning should be attended to, especially when put in the fractional form. Thus we easily see that $\mathbf{ab}^{-1} = \mathbf{a}\,b^2$, because the tensor of **b** is b^2 times the tensor of $\mathbf{b}^{-1}$. But we cannot equivalently write $a^2/\mathbf{ab}$, because this is $(a\,b)/\cos\theta$, which is quite a different thing.

Notice that $\mathbf{a}^{-1}\,\mathbf{b}^{-1}$ is not the same as $(\mathbf{ab})^{-1}$. The first is $a^{-1}b^{-1}\cos\theta$, whilst the latter is $a^{-1}b^{-1}\cos\theta$.

§ **110**. We know that in the equation

$$\mathbf{r} = x\mathbf{i}+y\mathbf{j}+z\mathbf{k},$$

where **r** is the vector distance of a point from the origin, the scalars are the lengths of the projections of **r** upon the axis. How should we, however, find them in terms of **r** algebraically? To find x we must operate on the equation in such a manner as to cause the **j** and **k** terms to disappear. Now this we can do by multiplying by **i**. For **i** is perpendicular to **j** and **k**, so that multiplication by **i** gives

$$\mathbf{ri} = x\mathbf{i}^2 = x.$$

Similarly, $\mathbf{rj} = y$ and $\mathbf{rk} = z$.

From this obvious case we can conclude what to do when the reference vectors are not perpendicular; for instance, in

$$\mathbf{r} = f\mathbf{a}+g\mathbf{b}+h\mathbf{c}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (31)$$

where **a**, **b**, **c** are any independent vectors. To find f we must multiply by a vector perpendicular to **b** and **c**, say **l**, so that $\mathbf{lb} = 0$, and $\mathbf{lc} = 0$. Then

$$\mathbf{rl} = f\mathbf{al}, \quad \text{therefore} \quad f = \mathbf{rl}/\mathbf{al}.$$

Similarly to isolate g and h, so that we get

$$\mathbf{r} = \frac{\mathbf{rl}}{\mathbf{al}}\mathbf{a}+\frac{\mathbf{rm}}{\mathbf{bm}}\mathbf{b}+\frac{\mathbf{rn}}{\mathbf{cn}}\mathbf{c}, \quad . \quad . \quad . \quad . \quad (32)$$

where **l**, **m**, **n** are vectors normal to the three planes of **b**,**c**, **c**,**a** and **a**,**b**. This exhibits explicitly the expansion of any vector in terms of any three independent vectors **a**, **b**, **c**, as the three edges of a skew parallelepiped. This case, of course, reduces to the preceding Cartesian case by taking **a**, **b**, **c** to be **i**, **j**, **k**, when **l**, **m**, **n** will also be **i**, **j**, **k**, or any scalar multiples of the same.

Observe the peculiarity that auxiliary vectors are used, each of which is perpendicular to two others, that is, to the plane containing them. These auxiliary vectors bring us to the study of the vector product.

(To be continued.)

THE EDUCATION OF THE ENGLISH ENGINEER.

The admirable little volume on "Engineering Education in the British Dominions," which has just been issued by the Council of the Institution of Civil Engineers, must be a source of lively satisfaction to those who, but a few years ago, had reason to fear for the pre-eminence of the "English engineer." In the sixties, when the appearance of the "techniker" and his success in many branches of engineering first began to attract attention in this country, we were enjoying to the fullest extent a system of engineering education peculiarly English in its utter lack of system. In November, 1868, in his inaugural address at the Edinburgh University, Prof. Fleeming Jenkin, describing the state of things which then existed in England, said, "Etiquette requires the engineer to show a certain reluctance to receive the pupil; and, in fact, the ordinary pupil is a sort of nuisance in an office, only tolerated in consideration of the fee which accompanies him. From personal experience I can declare that most pupils are so ignorant of algebra that they are not only incapable of working out a result for themselves, but actually cannot apply the simple formulæ which are given in engineers' pocket-books. The calculation of the solid contents of a wall is often beyond their powers. Their arithmetic is very shaky; and a knowledge of physics, chemistry, geology, or the higher mathematics, is wonderfully rare. . . No one teaches them anything, but they have the opportunity of seeing how some actual work is done; they see just how much mathematics is absolutely required, and they pick it up. . . The one point for them is to convince their masters that they are useful; and hence, notwithstanding their ignorance at starting, the neglect in which they are left during their pupilage, the absence of opportunities for improving their theoretical acquirements, many of them do become useful men. . . . But our success costs a vast expenditure of money and of brain, which could be turned to better purpose if we knew how to calculate the results to be expected from a given combination with some certainty beforehand. And not only does our ignorance cause much wealth to be wasted by the community on useless trials, but it prevents the trial of many new schemes, because the engineers or managers to whom they are submitted feel that they have no means of judging beforehand of the probability of success; so they, wisely in their generation, think they had better stick to the old plans, and in nine cases out of ten they are right; but the rejection of the tenth case is a dead loss to themselves and to the country." Such was the burden, not only of a "professor's" inaugural address, but of the many other similar addresses delivered at that period by "practical" men like Sir John Fowler and Mr. Thomas Hawksley. General Chesney, in reporting to the India Office on this subject, was even more emphatic. "The present mode of training an engineer, where a young man pays a fee to a civil or mechanical engineer for permission to work in an office or workshop, and pick up such crumbs of knowledge as fall in his way," said General Chesney, "is *not* education; and the cases must be very rare where persons, after undergoing such a training, will be found to pass an examination involving any knowledge of the principles of mathematics or theoretical mechanics. They usually take no knowledge of that subject into the office, and gain none there."

The great defect of the old system was *waste*. The pupil came to the workshop ignorant, and even with the best will in the world consequently wasted much time in slowly acquiring by "trial and error," and painful poring over pocket-books and the like, the elemental facts of his trade. No one taught him anything; and the same false start continued to act as an effective drag long after the shops had been left behind. Confronted by an entirely new set of conditions the majority of these self-taught engineers would have been found wanting, unable to "predetermine the characteristic" of the new development. Hence much waste of time, money, and brain tissue —a waste, be it remembered, affecting not only the individual himself but the country at large. There is, however, compensation in all things; and in a commercial community a method which results in waste of those two precious commodities, time and money, stands self-condemned. Fortunately, moreover, the cause of engineering education possessed able advocates at the very moment when the time was ripe for its advocacy, and, still more fortunately, it was a comparatively easy task to demonstrate to conviction to the business mind that, apart from national and individual interests, it was a question of pounds, shillings, and pence. Thus it has come about that while it is only some five-and-twenty years ago since the Indian Government made the discovery that engineers were not "brought up" but "dragged up" in this country, there is now some danger of over-educating. Almost within the last decade colleges for instructing engineers, civil, mechanical, mining, electrical, and chemical, have sprung up, and the institutions which previously possessed engineering courses have enlarged their scope and revolutionised their methods.

The old system of undiluted apprenticeship was peculiarly in consonance with the English way of looking at things. It had, moreover, all the force of a time-honoured and lucrative custom. That it should have collapsed so completely must be taken as a tribute to the logic of facts and the eloquence of sundry professors and eminent "practicians." Britons have always had a fondness for roughing it, or, rather, for making others rough it; and the process is undeniably a healthy one in its way. If the omniscience and proneness to mathematical formulæ said to be characteristic of the typical "techniker" survive a due course of "roughing it," these vices may be considered as inherent to the species. One apparently powerful argument in favour of the old method of evolving an engineer was that it turned out good men. Granting with all readiness that such was indeed the case, it might well have been asked whether still better results were not to be anticipated from a more enlightened system. A man who, in spite of all the hindrances which formerly existed, managed to attain a thorough grip of the theory and practice of engineering must indeed have been superior to the *average* man of that or any other day. Be the philosophical dictum that a great nation exists for the sole purpose of producing great men as true as it may, it is somewhat difficult to see where the advantage of erecting *artificial* obstacles to their production came in. The great engineers who succeeded in overcoming these artificial obstacles were necessarily giants of the first order of magnitude; but with fewer barriers we might have had more engineers of abnormal intellectual stature. Moreover, giants can take care of themselves; they come to the top in any case; and, with all deference to the aforesaid philosophical dictum, it is permissible to hazard the opinion that it is the *average* man who wants to be looked after. That the old order of things was favourable to the average man no one seriously contended.

When the advocates of technical training first began to make their voices heard in the land they were not unnaturally accused of wishing to manufacture engineers in college laboratories. Whether or no some such idea may not have lurked in the brains of a few ardent professors it is not now worth while to inquire, since the hastiest perusal of the remarks to be found at the head of the syllabuses of the various engineering colleges will show exactly what the object of college instruction is considered to be. At University College (London) it is understood that no college work "can render unnecessary a pupilage, or its equivalent, in the actual practice of the profession. . . . But the training given in the college will be found to be of value, not only directly, but also by enabling those who have gone through it to take fuller advantage of the opportunities afforded during a professional pupilage." At Cambridge, "although the workshops have been arranged on a considerable scale, the use of them is by no means intended to take the place of pupilage in a larger establishment." At the Mason Science College, Birmingham, "the whole of the teaching in the classes is practical and technical in its aim, no theory being introduced except such as has a direct bearing on the problems of professional practice, and no theories being taught until the facts upon which they are based have been fully explained." At Glasgow University we are told that "the work of the classes is not intended in any way to supersede the usual requirement of pupilage or apprenticeship in engineering;" and that "in drawing up the course the University have had in view to avoid altogether any competition with the offices of civil engineers or the workshops of mechanical engineers. . . ." In the United Kingdom, therefore, we are, it seems, all agreed

Digitized by Google

as to the futility of endeavouring to make engineers at college.

With such unanimity as regards the object to be aimed at it is not surprising to find that the curricula of our more important engineering training centres are very similar. They are, however, sufficiently diversified to ensure individuality. Nothing could be more detrimental to healthy and sustained progress than a crystallisation of methods. May no professional or engineering Confucius arise with a system of education so perfect as to render its universal adoption a mere matter of time!

As a specimen engineering curriculum, that of University College (London) may be taken. Here the complete course extends over three years, and comprises—

First Year.

Mathematics, Junior.	Experimental Physics.
Graphics, Junior.	Graphics, Drawing.
Mechanics.	Economic Geology.
Surveying.	

Second Year.

Engineering, Junior.	Graphics, Senior.
Machine Design and Drawing, Junior.	Practical Physics.
	Electrical Technology.
Mathematics, Senior.	Chemistry.

Third Year.

Engineering, Senior.	Mathematics, Senior.
Machine Design and Drawing, Senior.	Physics, Senior.
	Civil Engineering or Electrical Technology.
Engineering Laboratory.	

There is an unrestricted admission of students, many of whom only stay two years, and in some instance a year of apprenticeship is taken between the two years of college work, the remainder of the apprenticeship coming after the second year.

Provided an engineering student comes to college properly equipped, mentally and educationally, two years should suffice to further equip him with the scientific and practical knowledge necessary to enable him to make the most of the period of pupilage and the most of his subsequent opportunities. Those who can afford the time will not do amiss to prolong the college period, but except in special cases a three years' course is somewhat of a luxury. The sandwiching of a year of apprenticeship between two years of college life does not seem *primâ facie* likely to work well in practice, but rather to prove a disturbing element just at a period when the majority of us require to take a little ballast aboard. All paper examinations, whether competitive or qualifying, are to be regarded as necessary evils, to be borne with cheerful resignation in the hope that at some future eon in the history of the development of man something more to the point may be devised. But until that happy day arrives we should endeavour to weed out the "duffers" somehow, if only in the interests of the better qualified; and it would seem advisable and possible to adopt some golden mean between setting brain-racking entrance examination papers and allowing an unrestricted admission of students.

At King's College the course of mechanical engineering extends over three years, and there is no entrance examination. At the Central Institution the first year's course is the same for all, and the student then specialises electing to join the engineering, the physical or the chemical department, with a view of being educated as a civil or mechanical engineer, an electrical engineer or a chemical engineer; but studies in all four departments continue during the second year. Students who desire to go through a complete course and to take the diploma of the Institute have to pass an entrance examination. Besides the regular matriculated students those who have adequate knowledge are admitted when there is room to any courses they may select, and are allowed to work in the laboratories—an arrangement which would appear to solve the difficulty with which every popular institution with limited class-rooms and laboratories is sooner or later confronted, namely, how to prevent overcrowding without perchance weeding out a large percentage of admirable embryo engineers. At Finsbury Technical College the course extends over two years only, though students may remain longer.

The Royal Indian Engineering College at Cooper's Hill possesses peculiar interest to "educationalists," since it owes its existence to the fact that less than a generation ago the scientific training of engineers was such a comparatively unknown art in this country that the Indian Government, in despair of obtaining an adequate supply of suitable men by any means less heroic, undertook the education of its own engineers. From 1871 to 1883 the Cooper's Hill courses had reference solely to Indian engineering; at the present day the college opens its doors to all who can pay its fees, and the curriculum has been altered so as to make it attractive to students willing to look for a professional career elsewhere than in India.

At University College, Liverpool, the engineering course has a decidedly "civil" turn; and, as at Bristol, arrangements are made to permit of students entering some engineering works during the summer. At the Yorkshire College, Leeds, the distinguishing feature is that equal importance is attached to training for the scientific professions and to preparation for university degrees.

As a fitting conclusion to this *résumé* there will be found below a list of the colleges in the United Kingdom which are mentioned in the volume to which we have been alluding. It will be seen that there are no less than 33 colleges in the Kingdom where systematic instruction is given in the elements of the art of engineering, and that of these at least 16, or nearly 50 per cent., are new creations since 1870, the year in which the Council of the Institution of Civil Engineers issued their pamphlet on "The Education and Status of Civil Engineers in the United Kingdom and in Foreign Countries." It cannot be deemed other than satisfactory that such a number of centres of engineering education should now exist, that so many should have sprung up in response to the demand for scientific training; and that the governing bodies of these institutions should have so clear and so correct a conception of the scope and of the limitations of technical education as it affects the engineer. No doubt much remains to be done, but a vigorous and encouraging start has been made.

ENGINEERING EDUCATIONAL INSTITUTIONS IN THE UNITED KINGDOM.

1. University College (London).
2. King's College (London).
3. Royal College of Science and School of Mines.
4. Central Institution (1884).
5. Finsbury Technical College (1883).
6. Cooper's Hill College (1871).
7. Royal Naval College (Greenwich).
8. Crystal Palace School of Practical Engineering (1872).
9. Millard Laboratory (Oxford) (1886).
10. Department of Engineering (Cambridge).
11. Owens College (Manchester).
12. Manchester Technical School.
13. University College (Liverpool) (1882).
14. Yorkshire College (Leeds) (1873).
15. Bradford Technical College.
16. Durham College of Science (Newcastle).
17. Mason Science College (Birmingham) (1880)
18. University College (Bristol) (1876).
19. University College (Nottingham) (1881).
20. Firth College (Sheffield) (1879).
21. Sheffield Technical College (1880).
22. Hartley Institution (Southampton).
23. University College of South Wales (1882).
24. University of Glasgow.
25. University of Edinburgh.
26. Heriot-Watt College (Edinburgh) (1886).
27. Glasgow and West of Scotland Technical College (1886).
28. University College (Dundee) (1882).
29. Trinity College (Dublin).
30. Royal College of Science (Dublin).
31. Queen's College (Cork).
32. Queen's College (Belfast).
33. Queen's College (Galway).

THE COMBINED RESISTANCE OF CONDUCTORS IN PARALLEL.

The formula for finding the combined resistance of two or more conductors in parallel is well known to every student, and a very clumsy formula it is; so clumsy, in fact, that it is generally customary to treat of conductivities, and then translate back into resistances. The feeders which are laid by supply companies in the streets offer an instance of combined resistance, since they are made up, in many cases, of strips of copper side by side. If it is desired to put down a feeder of a

Digitized by Google

certain given resistance, making use of the standard size of copper strip, it will be necessary to calculate how many strips will be required; and since it is improbable that a whole number will make up the exact amount, the required resistance must be adjusted by using a short piece. To calculate the length of these by the ordinary formula is easy enough, but the following geometrical construction is very much more easy, and will give results quite accurate enough for practical purposes. On any convenient scale draw A B, representing the length of

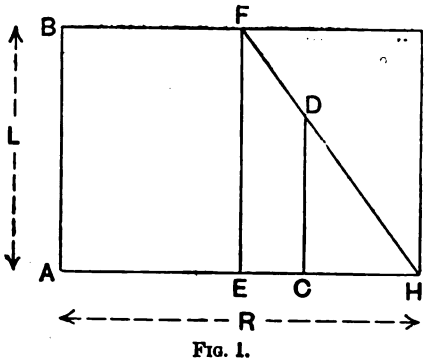

Fig. 1.

the feeder, and on any other convenient scale let A H represent the resistance of one strip. Let the required resistance be represented on this scale by A C. To find the additional length of conductor to be run in parallel in order to bring down the resistance from A H to A C, bisect A H at E, and draw E F perpendicular to A H, making E F equal to A B. Join F H from C, draw C D perpendicular to A H, cutting F H at D. C D will be the length required, and the combined resistance of A B and C D will be A C.

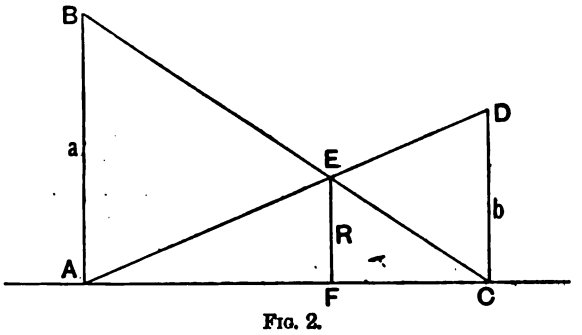

Fig. 2.

The two following constructions appeared in *Le Génie Civil*, May 2, 1891, p. 12:—"It is well known that the combination of several resistances in parallel is the reciprocal of the resistance of each circuit, and we will endeavour to describe a simple and rapid method of finding the combined resistance of a number of circuits, which was pointed out some little time back by the *Elektrotechnische Zeitschrift*.

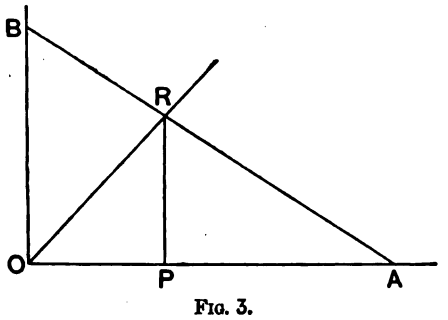

Fig. 3.

"Let a and b be the two resistances connected in parallel of which we wish to determine the combined resistance. Take two points, A and C, in a horizontal line, A C, and from A and C erect two perpendiculars, A B, C D, representing to any convenient scale the resistances a and b. Join B C and A D. From the point E where these two lines meet, let fall the perpendicular E F on the base A C. Then the line E F will represent the combined resistance r, of the two resistances a and b. The value of r may also be found by the well-known algebraical expression

$$r = \frac{a\,b}{a+b}.$$

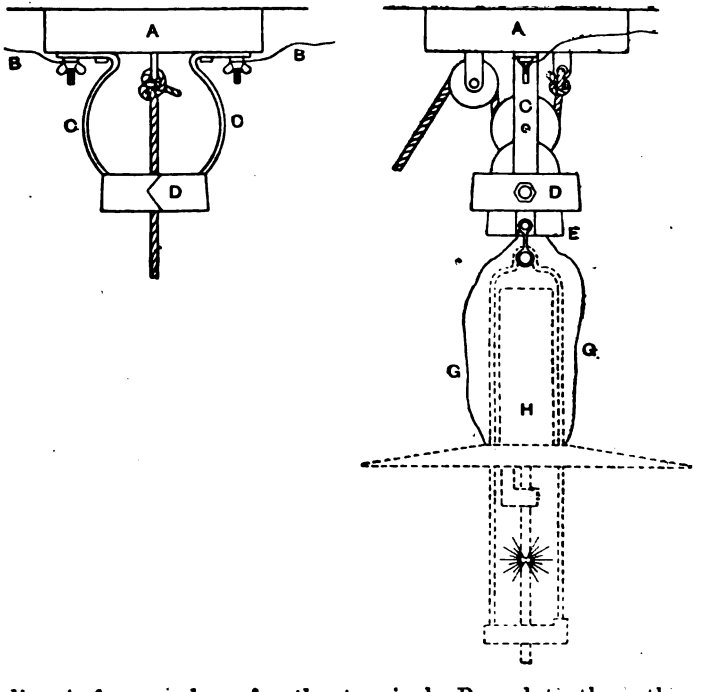
"If there are more than two circuits we can then proceed to take the value r and the third resistance, and repeat the same operation as before, and so on, until the circuits are exhausted."

In *Le Génie Civil*, Sept. 22, 1891, p. 362, the following method is pointed out:—"Let O B and O A be drawn at right angles to each other, and let O R bisect the angle A O B. To any suitable scale measure off O B and O A as representing the resistance in shunt. Join A B, cutting O R at R. From R let fall R P perpendicular to O A. Then R P shall be the resultant resistance required. This is easily seen, since the angle A O R being 45deg., R P = O P and

$$\frac{1}{RP} = \frac{1}{OP} = \frac{1}{OA} + \frac{1}{OB}."$$

AUTOMATIC SWITCH FOR SUSPENDED ARC LAMPS.

A switch for placing an arc lamp in circuit by the act of hoisting it has been designed by Messrs. Wagg and Hudson, and has been extensively used at Woolwich Arsenal. A wooden



disc, A, forms a base for the terminals, B, and to these the leads are attached. Springs, C C, hold a divided ring, D. A conical wooden plug, E, is fixed to the pulley which supports the lamp, and on the surface of this plug metal strips are fastened. The wires G connect these with the terminals of the lamp. When the lamp is raised, the conical plug opens the half rings, and completes the circuit through the lamp. On lowering for trimming, the rings close and maintain the circuit. Modifications of this arrangement allow wire rope to be used, and for parallel working the rings are arranged so that they do not close when the lamp is lowered.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

FRIDAY, December 18th.

PHYSICAL SOCIETY.

5 p.m. Ordinary Meeting. Paper to be read: "On Interference with Alternating Currents." By H. Kilgour.

JUNIOR ENGINEERING SOCIETY.

8 p.m. Ordinary Meeting. Paper to be read: "Engineering Practice in the Cleveland and North-East Coast Districts. By S. H. Wells, Wh.Sc., Stud. Inst. C.E.

DOES ELECTRICITY EXIST?

Discussions on the exact nature of electricity are too often to be deprecated as being mere waste of time, temper and brain tissue. Our premises are as yet too shaky to permit of the building up of a solid superstructure of logical deductions; even the giants soon get out of their depth, while the rank and file flounder from the commencement. These remarks have, however, only a strictly local application. Across the Atlantic a determination of the exact nature of that which we call electricity would probably make an appreciable difference in the net profits of many an electricity supply company. If electricity is a manufactured article, the State tax-gatherer will in most cases deal tenderly with central lighting stations. But before this happy consummation can be attained, the law must decide, firstly, whether or not electricity is a form of energy, and if so whether transformation of energy constitutes a manufacture; secondly, whether or not electricity is a substance, and if so whether it can be held to be manufactured at the generating centre.

While not presuming for a moment to offer any material assistance in settling this delicate question, we venture to make one or two observations on the subject *apropos* of the interesting series of articles which is commenced by Mr. H. E. Harrison

Digitized by Google

in our present issue. We have requested Mr. HARRISON to place before our readers a brief and elementary account of the principles underlying the measurement of alternating currents, with special reference to the effect of choking coils on the apparent current, and the effect of an inductive circuit on ordinary electric meters. Mr. HARRISON takes his stand with a redoubtable ally when he sides with Dr. OLIVER LODGE, to whose "Modern Views of Electricity" he alludes. So imbued has electrical science become with analogies, that we often forget whether the trains of geared wheels which are so ingeniously and satisfactorily used to explain electrical phenomena are a pure analogy, a working hypothesis, or an attempt to explain an actual mechanism which may be assumed to exist on a subtle and infinitesimal scale. Dr. LODGE has held at different times, or now holds when in different moods, or uses on different occasions, two theories which appear to us to be distinct. In one of these, particles of ether—whether atomic, or molecular, or vortical, matters not—are geared together; and electrical phenomena are lucidly explained by the relative motions, transmissions of motions, shear and slip of these particles. In the other, electricity is treated as a substance, having perhaps a molecular structure. Both of these theories are alluded to in the opening paragraphs of Mr. HARRISON'S article; and, strictly for the purpose of clearly explaining the nature of a current, he adopts the stream of particles as a suitable hypothesis. When students are thus clearly warned that the language of hypothesis is being used, no exception can be taken to the expression "quantities of electricity." The definition of a coulomb naturally follows, and Mr. HARRISON seizes on the idea to express in most forcible and unmistakable terms the difference between quantity and current. It is, therefore, with no intention of criticising the accuracy of his language that we question whether in a more general and scientific sense the idea of a coulomb is necessary, and whether the existence of a substance called electricity is tenable.

There was a time when heat was with little or no hesitation pronounced to be a substance. We have heard that somebody holds that the undulatory theory of light is tottering, and must shortly fall ignominiously. A public lecture was given not long ago to prove that sound is due to the emission of small particles, and that the modern theories of acoustics are completely illusory; but no one, to our knowledge, teaches that heat is a "thing." Metaphysics are excluded from our columns for obvious reasons, and there is no occasion to discuss the idealistic and materialistic philosophies. An American thinker has defined "a thing" as "is-ness," and "matter" as "is-ness possessed of some-whatness." That is quite sufficient for our purpose. Though heat is not matter it is a mode of motion of something, and this may be matter or ether according as we consider the heat in a body or radiant heat. We can draw no line between radiant heat and light, and there is no line between light and electro-magnetic disturbances. There seems, then, to be no reason why we should, when speaking scientifically, say that electricity is ether, since we do not say that sound is air. If it be conceded that electrical phenomena are due to motions of or strains in ether, why should electricity be considered as a substance when it is readily accepted that sound is mere motion? This being so, what becomes of the coulomb? In another column we allude to several traditions which were created by the electrician and have been unconsciously adopted by the electrical engineer, who invests them with an unreal value, and who should now cast them aside. The coulomb likewise seems to be an ancient residuum of the fluid theories of electricity which have been abandoned by an overwhelming majority, though perhaps not by all students of electrical science. Taking an excellent illustration, which Mr. HARRISON will give in the course of his articles, namely, the passage of visitors through a turnstile; when a hundred persons have passed, they can be collected, counted, and seen; they exist. When a coulomb has passed through a voltameter, where is it? What we really find is a result of the passage of a certain number of amperes during a certain period of time. The grammes of silver are not coulombs any more than the mud on a door-mat can be said to be a crowd because it has been caused by the passage of a number of people. If, in our metaphorical or hypothetical language we wish to clearly express a current, we are forced to say that it is as though something flows. How much of that thing flows? and how do you measure how much? The coulomb naturally presents itself; and for the purpose of concentrating the thoughts of a student it serves a very useful purpose. A thermal unit of heat is a much more important idea than a coulomb, because there is no word for a thermal current. The rate of transfer of heat is an everyday matter of calculation, and the processes are as simple as possible; but some ill chance might have suggested a thermal current, and temperature might have been called thermo-motive force. Fortunately, the paths of heat are not so tortuous as those of electric currents, and the transfer is rarely by any other than a fairly straight route.

The relations which HERTZ and others have indicated between electrostatic and electromagnetic disturbances introduce some difficulties into the otherwise simple considerations of pure static electrification and simple magnetism; and from the point of view of mental imagery, it seems more easy to conceive that every molecule is a minute magnet than to contemplate the Amperian hypothesis that magnetism is due to the circulation of molecular electric currents. If it be granted that every molecule is a magnet, it is only necessary to move it in order to produce both electromagnetic and electrostatic phenomena. In fact, it is a general law that the continuous motion of magnetic lines produces electrostatic force, *i.e.*, electromotive force. This is proved by arranging a conductor along the lines of electrostatic force, since a current is produced in the wire directly the circuit is closed. The only reason why such currents are not observed in ordinary electrostatics is because the mere introduction of the conductor into the electric field entirely alters the condition of the latter, since, as a rule, the energy involved in electrostatic effects is infinitesimally small. Theory indicates that if the wires used were sufficiently thin, and the instruments delicate enough, electrostatic phenomena could be investigated by electromagnetic instruments; and we can consider electrostatic effects as primarily due to the motion of lines of magnetic force due, say, to molecular magnets. Why, then, do we need the idea of something called electricity? This point of view is perceptibly strengthened by the remarkable investigation which has been recently made at the Royal Institution, whence the spirit of Discovery seemed to have fled, giving place to Discourse. The behaviour of liquefied oxygen in a spheroidal state was remarkable enough; only a year or two ago a speaker at the Institution of Civil Engineers raised a titter when he said that under intense pressure, liquefied gas could be seen in drops or jets on the walls of a coal mine; and the pouring of liquid oxygen from one tumbler to another seemed almost equally incredible. The experiment was wonderful, but was of little or no scientific value. But now the liquid gas, placed in a crystal dish, and held beneath the poles of FARADAY'S historical electro-magnet, was raised in a mass, and hung to the

Digitized by Google

metal like a handful of iron filings. FARADAY showed that oxygen was magnetic, and the loss of magnetism when iron is heated is well known; but such a result as that which Prof. DEWAR described to the Royal Society last week is a startling one. Indirectly at first sight, but perhaps closely connected with this, is the suggestion of Prof. HOUSTON that the actinic action of light is a species of electrolysis. The decomposition of carbon dioxide by chlorophyll in a living leaf under the influence of light, the absorption of carbon, and the setting free of oxygen may be an electrolytic action, and seems to be accompanied or determined by a minute difference of potential. It is more easy to imagine that chemical affinity and magnetic attraction are identical than that they are two distinct forces. Magnetism may lurk in unsuspected materials and in unknown conditions. But magnetism does not "exist"; it would appear to be the property of a molecule, whereby a strain is set up in the neighbouring ether. If this is so, leaving THALES and his amber, the innermost recesses of electrical science should be studied from the electromagnetic point of view; and whether electrostatics can be successfully attacked from that quarter or no, the idea that electricity is a substance, and that we can have lumps of it measured in coulombs, will probably vanish without a regret.

THE PRINCIPLES OF ALTERNATE CURRENT MEASUREMENT.

BY HUGH ERAT HARRISON, B.SC.

Introductory.

The measurement of electrical quantities seems to cause great perplexity to many young electricians, and especially to those who have received no scientific training outside their special subject.

The older fluid theories having proved altogether insufficient, and the true nature of electricity being still undetermined, the writers of text books and teachers frequently abandon all reference to such theories, even to the extent of not using the useful analogies which at least are suggested by them. An attempt is made to teach *what electricity does*, without any reference to *what electricity is*. The abstract is mistaken for the concrete, and confused ideas are the natural result.

It is generally extremely difficult to describe anything new without using, in a metaphorical sense, the name of something which resembles it in some of its chief properties. The retention of such words as "current," "pressure," and others, at all events, indicates an analogy, however carefully any special reference to it may be avoided.

No book has been published, for some years past at all events, which has done so much to help the student to a clear conception of his subject as Dr. Lodge's "Modern Views of Electricity." The portion of the volume which treats of electricity in motion explains at length a working hypothesis of the nature of electricity, and shows how many electrical phenomena may be accounted for. The hypothesis is, perhaps, very far from the truth; but it gives the reader a mental image of what may be happening, and is, therefore, a most valuable aid to memory.

Electricity is assumed to be the luminiferous ether, or rather electrical effects are assumed to be produced by ether in certain conditions. Ether pervades everything, interstellar space and matter alike. It is incompressible, though capable of distortion, and its properties are modified by the presence of different kinds of matter. The particles of ether, to use an easily understood expression, are geared together in some way, so that in space or within insulating material one particle cannot move past another, though it may rotate; but the presence of a conductor so alters the state of these particles that they may move about among themselves in much the same way as particles of water do. A current of electricity through a conductor is assumed to be a stream of these particles. This is not the only hypothesis made as to the nature of an electric current, but it is adopted here as the one most suitable for the present purpose of considering certain points in connection with the measurement of some electrical quantities and the units and standards employed.

The Coulomb, the Ampere.

If an electric current is flowing round a circuit, A B (Fig. 1), the quantity of electricity in motion is unknown, the actual velocity with which the ether particles or the electricity passes through any section, S, of the conductor is also unknown. The speed may be thousands of miles per second, or it may be but the fraction of an inch per hour. One thing, however, is clear; if the current remain constant, twice the quantity of electricity will be carried across S in two seconds that will be carried in one. Whether the speed of the current is so great that the same individual particles are carried round the circuit

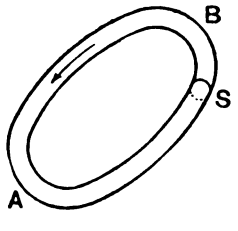

FIG. 1.

many millions of times in a second, or so small that hours elapse before a particle again crosses, matters nothing. The same identical quantity passing six times is considered the same thing as six times the quantity passing once.

Two quantities of electricity can be compared by chemical means. If quantities can be compared, a unit or standard by which all other quantities of the same thing shall be measured can always be selected.

Let a portion of the solid conductor A B, Fig. 1, be replaced by a solution of nitrate of silver in water, L, Fig. 2; if the direction of the current is that indicated by the arrows, silver will be deposited on the surface M N, by which the electricity leaves the liquid and re-enters the solid; to keep the strength of the solution constant during an experiment, the surface P Q must be made of silver, when metal will be found to be carried *into* at the same rate as it is caried *out of* the solution.*

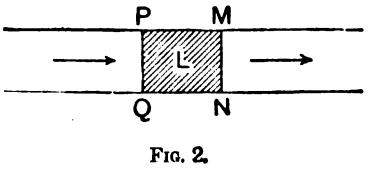

FIG. 2.

The weight of silver deposited is proportional to the quantity of electricity which crosses the surface M N, and the practical unit of quantity is called the coulomb.

A coulomb may be defined as that quantity of electricity the passage of which deposits 0·001118 gramme of silver on the surface M N.

Having fixed upon the *unit quantity of electricity*, or coulomb it is easy to get the *unit of current*, or ampere; but as confusion is frequently caused by an indiscriminate use of the names of these totally different units, the distinction between them must be emphasised, and the inevitable parallel drawn between water and electricity.

A pound of water is a perfectly definite quantity, and may be taken as *unit quantity of water*. If, however, a stream of water is flowing in a conduit and a measure of the current is required, a new unit must be introduced. Clearly the current cannot be measured in pounds only, for the conduit may contain exactly as many pounds of water whether it is flowing in a current or is at rest. The magnitude of the current is

* For the method of using the silver voltameter, see *The Electrician*, Vol. XXVII., p. 325.

Digitized by Google

measured by the quantity which flows; and *unit current of water* may be defined as a flow of one pound per second. The point to be specially noted is this: a current of water cannot be measured by the single unit of quantity, the pound. The unit is a compound one, and involves the *unit of time* as well as the *unit of quantity*.

"A current of ten pounds" affords no clue to the magnitude of the current, but "a current of ten pounds per second" gives a perfectly definite measure of the current as already explained.

Mutatis mutandis, what has been said for water applies equally to electricity.

The coulomb is a definite quantity of electricity; but a current of electricity cannot be measured in coulombs alone, for the same reason that a current of water cannot be measured in pounds alone. But, if the current flowing (Fig. 2) has to be measured, this can be done by finding out how many coulombs flow across the section S in one second; the measurement of the rate at which the coulombs pass is actually made by the chemical means indicated in Fig. 2.

For commercial purposes the Board of Trade says, "That an unvarying current which, when passed through a solution of nitrate of silver in water, in accordance with the specification attached to this report, deposits silver at the rate of 0·001118 of a gramme per second, may be taken as a current of one ampere."

This definition is, in effect, primarily a definition of the "coulomb" from which is immediately deduced the definition of the "ampere," although the Board of Trade neither specifically defines nor, indeed, ever uses the word coulomb.

"Quantity of current" is an expression frequently used by working electricians sometimes in the sense "strength of current," at other times to mean "quantity of electricity." The latter use probably arises from the fact that the discharge from a secondary battery may be measured in "ampere hours;" an ampere hour, meaning the quantity of electricity delivered by a current of one ampere flowing for one hour, is the same thing as 3,600 coulombs, and is, of course, quite a different thing from the ampere, which denotes the rate at which electricity is being delivered.

When, however, the meaning of an expression is ambiguous its use should be most carefully avoided.

The Alternating-Current Ampere.

If the ever-varying value of the electromotive force set up in the armature of an alternating-current dynamo machine, whose armature coils are not wound on iron cores, be plotted in the form of a curve, E (Fig. 3), of which the abscissæ represent

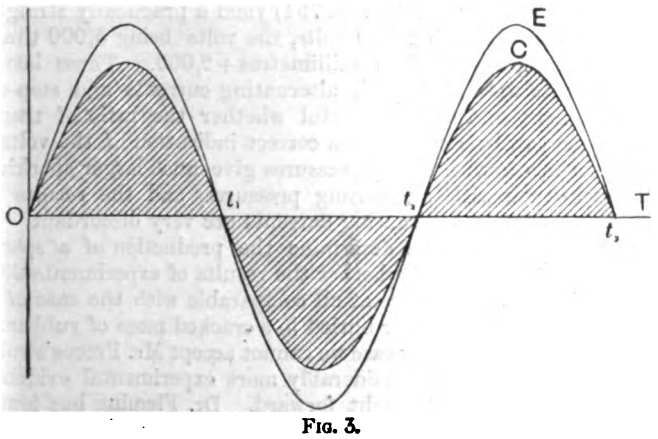

Fig. 3.

intervals of time and the ordinates the corresponding value of the electromotive force, it will be found that such a curve does not differ appreciably from a curve of sines. One direction along the conductors being arbitrarily considered positive the ordinate representing an electromotive force acting in that direction is considered positive and drawn above O T; but an electromotive force acting in the opposite direction is considered negative, and its ordinate drawn below O T, the same convention is also adopted to show the direction in which a current flows along the conductor.

Suppose the terminals of the machine to be joined through some non-inductive circuit of resistance R, then the curve C representing the current at any instant, both in magnitude and direction, can be drawn by multiplying the E.M.F. ordinates by 1/R, since Ohm's law, rightly interpreted, holds as well for an alternating as for an unvarying current.

The quantity of electricity carried across a section of a conductor is equal to the current multiplied by the time it has flowed, so that the shaded area, enclosed by the current curve and O t_1, gives the number of coulombs so transferred during the time, O t_1, the current has been flowing in one direction. At t_1, the current reverses and flows in the same manner as before during an equal interval of time but in the opposite direction, so that an equal number of coulombs, shown by the area included by the current curve and t_1 t_2, is carried back across the section in the reverse direction. It follows, therefore, that no matter how long the machine has been running, the greatest quantity of electricity that can ever have been permanently transferred across the section is equal to one of these areas; and this, indeed, occurs only if the current is stopped when at the point of reversal, and one more pulse has passed in one direction than in the other.

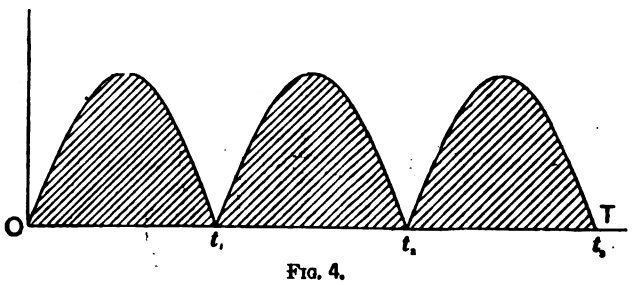

Fig. 4.

Clearly, then, the silver voltameter is useless for measuring such a current; as a whole, as much silver would be carried in one direction as in the other, and since the reversals usually take place hundreds or thousands of times in a minute, it is out of the question to obtain any indication at all of the current from this instrument.

But the current may, after leaving the armature coils, be sent through a commutator from which the pulses always pass in the same direction into the external circuit (Fig. 4). This being done, the current beyond the commutator will be represented by Fig. 4; if it is now passed through the voltameter, silver will be deposited, and after any suitable interval of time the deposit will measure the number of coulombs shown by the areas drawn for the same interval of time. If the number of coulombs registered by the voltameter be divided by the time, the quotient, which is the *time average* of the current that has passed during the interval, gives the value of the unvarying current which would have delivered the same number of coulombs in the same time.

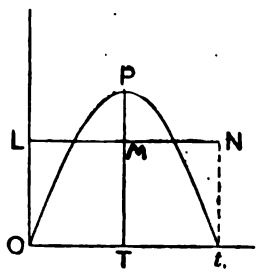

Fig. 5.

If O Pt_1 (Fig. 5) represents a single pulse of the current whose value varies from zero to a maximum P T, and similarly L N, the unvarying current which would have deposited the same weight of silver, then the area O L Nt_1 equals the area O Pt_1, and M T is the average height of the curve O Pt_1, or, since Ot_1 represents time, *the time average of the current at each instant.* In the case under consideration, O Pt_1 is a sine curve, and M T equals 0·637 P T.

THE INSULATION OF ELECTRIC WIRES AND CABLES.

The long interval which will elapse between the reading of and discussion on Mr. Preece's Paper * on the Specification of Insulated Conductors, should give plenty of time for manufacturers to prepare matter for a good debate, and to carefully reconsider their methods of describing their wares. The idea of specific insulation which is prominently brought forward in this Paper forms the subject of a section in Mr. Kempe's book on Electrical Testing. It is open to question whether, having the words "conductivity" and "resistance," we need a third word. Many people shrink from using such numbers as $1{\cdot}09 \times 10^{25}$, for fear that a decimal place may get wrong in their calculations, and, while the idea of a cubic quadrant seems at first sight to be an exaggerated application of the C.-G.-S. system in a most pedantic form, it turns out, by a most fortunate coincidence, to be exactly that dimension which will give us round numbers with the fewest possible decimal places, to express the resistance, or, as Mr. Preece calls it, the insulation of dielectrics. Mr. Preece's table, which should include recent measurements of gutta percha, and, if possible, the compounded braid and tape with which electric light cables are covered, ought to be embodied in all engineers' pocket books and other works of reference. It is true that in practice we generally regard insulators as offering so much "insulation," and not so many ohms or megohms, since the leakage current is as a rule negligible; but, on the other hand, it is only by considering the leakage current that we can form a definite idea of the real degree of insulation of a conductor, which is somewhat loosely termed its "efficiency," near the end of the first paragraph of Mr. Preece's Paper. This point is an eminently practical one; and when once it is realised that it is the leakage current and not the megohms per mile that we want to know, it becomes difficult to see why manufacturers should have adopted the mode of classification at present in vogue, which results in a 61/12 and a 7/20 cable being placed in the same category merely because they are both given an insulation resistance of 5,000 megohms per mile; their "efficiencies" being, however, of a widely different order. This practice of talking about megohms per mile, like the use of binding screws, is a legacy bequeathed to us by the old school of electricians, an interesting relic of submarine cable construction; it is not only useless, but misleading in engineering work.

Many lists contain no information as to the diameters of cables; although such information might be considered as the first practical step in the direction pointed out by Mr. Preece. But it is not the diameter so much as the thickness which really gives the useful information. We do not remember any list giving the thickness. Given a "class" which is found to be generally satisfactory, the thick insulation of the large sizes becomes wholly unnecessary electrically, while in the smallest sizes the covering is often mechanically too thin. The mechanical qualities of insulating materials have not received much attention in Mr. Preece's Paper. There are at least three mechanical considerations—the strength of the covering to protect the conductor from contact with other conductors forced against it, as, for instance, when a telephone wire falls across an overhead wire; the strength needed to stand dragging into tubes, &c.; and, lastly, the flexibility needed to ensure freedom from cracks when the cable is handled during work, and when in its final position it is bent round sharp corners. More than one engineer of our acquaintance is of opinion that some mechanical test should be made especially for flexibility, and some suggestions will probably be forthcoming when the Paper is discussed. An excess or a deficiency of covering is detrimental to mechanical strength. The former is to be found in the insulation demanded for overhead wires by the Board of Trade, and the latter in some of the small wires used for house work.

The small circumference of a No. 19 wire enables a fair insulation to be obtained by means of a very thin and weak skin of india-rubber; but when a pull is given to the wire by grasping the covering, the braiding will sometimes stretch and extend the rubber, which sooner or later cracks. No. 19 is indeed much too small for ordinary wiring, and No. 17, if not No. 16, should be the smallest size allowed. The price of No. 19 is about 25 per cent. less than that of No. 17, and 32 per cent. less than No. 16 of fair quality. The difference is, of course, greater in low classes. The cost of insulated wire and cable comes to about 7s. 6d. to 8s. per lamp for the ordinary run of work, and one-half of this may be taken as small wire. The difference between No. 19 and No. 16 amounts then to only one or two shillings per lamp, or about *five per cent.* on the whole cost of wiring. Where greater flexibility is needed, the finely-stranded cables of 3/22 or 7/25 are very useful, and the use of smaller sizes, such as 18 or 19, should only be permitted in special cases for wiring fittings which will not take larger diameters. Between an inferior class of No. 19 and a fair class of No. 16 there is a difference of a hundred per cent., and this makes the need for accurately specifying the quality the more important. The use of smaller wire than No. 18 is prohibited by several London supply companies.

The great thickness of insulation required for high voltages by Mr. Preece and by the Board of Trade is quite unnecessary as an insulation, and is intended only to afford protection against sparking through cracks. It is by no means essential that the whole thickness should be made up of first-class insulating material, and experiments are needed to settle how disruptive discharges behave when they take place through cracks. A good coating of pure and of vulcanised india-rubber near the wire, and the rest of the thickness made up of strong fibrous material well "compounded," would seem to be the best arrangement. The insulation would be provided by the one, and mechanical strength by the other. Thoroughly well-woven braiding cannot crack like a homogeneous sheath of rubber. It is far stronger in every way, and a tolerable insulator.

In dealing with the question of sparking distance, the virtual alternating volts should not be taken, but the maximum. For most dynamos, especially those without iron in the armature, the maximum volts may be taken as one and a-half times the virtual. In such dynamos as those recently described by Mr. W. B. Lewis (*The Electrician*, Nov. 27, p. 91) some idea as to the maximum should certainly be obtained. The experiments of De la Rue and of Sir W. Thomson showed that for low volts the sparking distance was approximately as the square of the volts. Beyond 1,500 the curve connecting volts and sparking distance is practically a straight line. This line produced cuts the axis at about 700 volts. The volts may, therefore, be represented by 4,000 times the sparking distance in millimetres + 700. The experiments described by our German correspondent (*The Electrician*, Vol. XXV., p. 754) yield a practically straight line, passing through 2,000 volts, the volts being 5,000 times the sparking distance in millimetres + 2,000. These latter experiments were made with alternating currents and step-up transformers, and it is doubtful whether the ratio of transformation can be accepted as a correct indication of the volts.

Experiments with steady pressures give much larger sparking distances than with alternating pressures, and the results of observations with alternating currents are very discordant. A large number of causes determine the production of a spark, and it is very doubtful whether the results of experiments with points, balls, or plates are at all comparable with the case of a wire of indefinite diameter buried in a cracked mass of rubber or other insulator. In any case we cannot accept Mr. Preece's rule-of-three sum without considerably more experimental evidence than has yet been brought forward. Dr. Fleming has found that the 2,400 volts of the London Electric Supply Company will not spark across $\frac{1}{32}$nd of an inch (·794 millimetre), and as no authentic example of an accident from this cause has been recorded, the matter can well wait until the general discussion is taken. Two equally important, but still more obscure failures of insulation are to be found in the actual piercing of solid dielectrics, and in the "creeping discharge," which is very marked at pressures of 20,000 to 30,000 volts, but which seems to exist in another form in the presence of moisture at 100 or even 50 volts.

Mr. Preece has not clearly stated how he proposes a manufacturer's list of cables should be drawn up; but we gather

* *The Electrician*, Dec. 11, p. 146.

Digitized by Google

indirectly from the opening paragraph that what he calls the efficiency should be the same for all cables of one class. This would be a thoroughly rational system, and in exact harmony with the well-known rules for the insulation of complete circuits, viz., that the insulation should be inversely as the number of lamps, or, more simply, that the leakage current must bear a constant proportion to the main current. A mile of cable offering 1,000 megohms per mile allows under a pressure of 100 volts a leakage current of $\frac{1}{10}$th of a micro-ampere. If this be considered suitable for a cable of, say, 7/16s, carrying 20 amperes, the insulation might be defined by the rule that the leakage current per mile must not exceed one two hundred millionth part of the working current. Other cables insulated to the same degree of "efficiency" would have an insulation proportional to the square root of their diameters, since the leakage depends on the circumference, while the carrying capacity depends, in most practical work, on the sectional area. But we are at once met by the absurdity of considering such a leakage current as one ten-millionth of an ampere. If it were a hundred or a thousand times larger or smaller no one would be any the wiser; and though the system may be truly rational it can hardly be said to be practical, unless in an indirect sense to which we shall allude presently. The Board of Trade demand for "continuous insulation" 100,000 ohms per mile for every volt, which limits the leak to ten micro-amperes at 100 volts, or one hundred times the leakage assumed in our example. A cable of the unheard of insulation of 10 megohms per mile would therefore meet the Board of Trade requirements for 100 volts. It appears from the very practical letter which we recently received from Mr. Sutton* that cables of a lower class than 150 megohms per mile are not adapted for testing under water, so they must be taken for what they are worth without the description afforded by such tests. The deeper we plunge into calculations based on these megohms, the more impractical does this mode of specification appear, and there is little doubt that Mr. Sutton's observation gives the real and only meaning, viz., that "for a given thickness of insulation, the megohm test is a true indication of the quality of the material and the workmanship." Mr. Sutton offered a timely warning against the acceptance of the diameter of the cables as an indication of the thickness of the insulation; and although the value of the mechanical protection afforded by tapes and braiding yarns is often underestimated, we should like to see the thickness both of the insulating material and of the outer serving given in the makers' lists. We have tried to apply Mr. Kempe's approximate formula to the list of a well-known firm of cable makers; but having only the outside diameter to go upon, the values of the "specific insulation" are quite discordant, a class which is described as "600 megohms per mile" giving very irregular specific insulations, varying from ·58 to 1, and showing no connection between the quality and the thickness, as might be expected. Mr. Sutton's remarks as to the true use of the megohm test show that this, in conjunction with information as to the thickness of the insulating material, will, by the aid of Mr. Kempe's approximate formula, give a good idea of the electrical qualities of a cable or wire; and it is to be hoped that in future lists the value of σ will be given at once, and thus save the trouble of working it out. The megohms per mile should vary throughout each class, and need not be given when once the new system is understood; or, at the most, it might be quoted for one particular size, say 7/16s in each class. Not only the megohms, but the specific insulation depends on the way in which the test is carried out. Mr. Preece puts forward the clear statement that one minute is universally accepted as the period of electrification. This should be taken as a challenge to any makers who test in another manner. If they desire to continue their present system, they should come forward at the discussion and give their reasons. The water test, it must be remembered, can only be applied to certain kinds of cable, and is not applicable to various systems of conductors used for supply mains.

The table of values of σ of different kinds of electric light cables given in Mr. Preece's Paper would have been much improved by the addition of the "classes" in which they are at present placed; thus the Silvertown examples appear to be something very different from their well-known qualities; even their 19/15 L, the most expensive class, comes only to $\sigma = 7$, taking the diameter ·758 given in their October list, while in Mr. Preece's Papers we have σ equal to more than 11. We must not trench on the subject of price; it is considered improper to compare prices too closely or analytically, but the table would also have been still more interesting if it had related to cables of about the same price.

With regard to the first clause of the specification proposed by Mr. Preece, we cannot but think that it savours too much of the electrician, and too little of the engineer. The conductivity of the copper is a matter of no importance whatever to the consulting engineer or to his client when the fall of volts is specified as it always should be. This is clearly another relic of telegraphic practice and should be set aside as an unnecessary complication. The result of employing a low conductivity only means that two or three per cent. greater weight of metal will be used. The contractor must, of course, beware of miscalculating his resistances, but an error quite comparable to that due to variation of conductivity is often neglected, viz., the effect of the "lay" in increasing the weight but in diminishing the resistance. Mr. Connolly recently gave some information on this subject (*The Electrician*, Vol. XXVI., p. 435), but even he had not considered the exact difference until we called attention to it.

The 7th, 8th, 9th, and 10th clauses in the specification refer to matters which we hope will be clearly dealt with in makers' lists. The 8th clause should not supersede the quotation of the over-all diameter of the cable, which it is often very necessary to know. The method of testing is alone a subject that might be discussed at great length, and here Mr. Preece's advice is thoroughly in accordance with engineering practice. There is unfortunately no factor of safety as in boiler or steam-pipe work. A test of from 1½ to twice the working pressure is the ordinary custom in the boiler-shop, and amounts to from one-third to one-quarter the assumed bursting pressure. A test for 24 hours at 1½ times the working volts, the cable being handled either by coiling in and out or recoiling in the tank, should be an ample test. A test made when tightly coiled on a drum—perhaps coiled while warm—is but little guarantee of the future behaviour of a cable. We learn with great satisfaction that two or three of the leading makers of electric light cables intend to revise their lists; and whether they do so at once, or wait until this Paper and the one promised by Mr. Alexander Siemens have been discussed, Mr. Preece's communication cannot fail to have a most useful effect in calling the attention of both makers and users of insulated cables to points which are of such great importance to the efficiency and safety of electric lighting.

* *The Electrician*, November 27th, p. 98.

THE FRANKFORT EXHIBITION.—XVII.

(FROM OUR SPECIAL CORRESPONDENT.)

The firm of Lahmeyer, of Frankfort, has solved the problem of producing a safe compound motor in a very ingenious way. The danger of a reversal of polarity on suddenly increasing the load is avoided by using two magnetic fields acting on the same armature, the shunt and series coils being wound on different cores. The connections of the circuits are diagrammatically shown in Fig. 1. The shunt magnets *n n* are of much larger dimensions than the series magnets *d d*, and the field produced by them is the stronger even when the series magnets are highly saturated by an excessively heavy main current. The machine has been christened the "long-lead" motor, since the volts lost in the leads, which would have a very marked effect on the speed of a pure shunt motor, are here inoperative as a factor producing variable speed with varying load.

The Offenbach-Frankfort transmission of power, although not calculated to impress the public as much as that from Lauffen, was of interest to engineers. During the Exhibition direct current alone was used, but soon after its close, Herr Lahmeyer was enabled to use the three-phase current.

First, as regards the direct current. At Offenbach, 6¼ miles by the wires from the Exhibition, there was a four-pole drum

Digitized by Google

armature 50 kilowatt dynamo. The magnets were excited by a 110 volt current, and the excitation regulated by a resistance so that a constant voltage of 2,000 was always maintained at the terminals of the machine. The transmission wires were ·24 in. in diameter, and the loss of pressure in the leads with the maximum current of 25 amperes was about 200 volts. The between 0 and 25 amperes, a constant pressure of 2,000 volts was supplied to the high-pressure brushes of the "dynamotor" or continuous-current transformer at Frankfort. The drum armature of this machine has, as usual, two windings and two commutators, for high and for low pressure. The machine is four-pole, and the initial excitation is given by a few high-pressure series

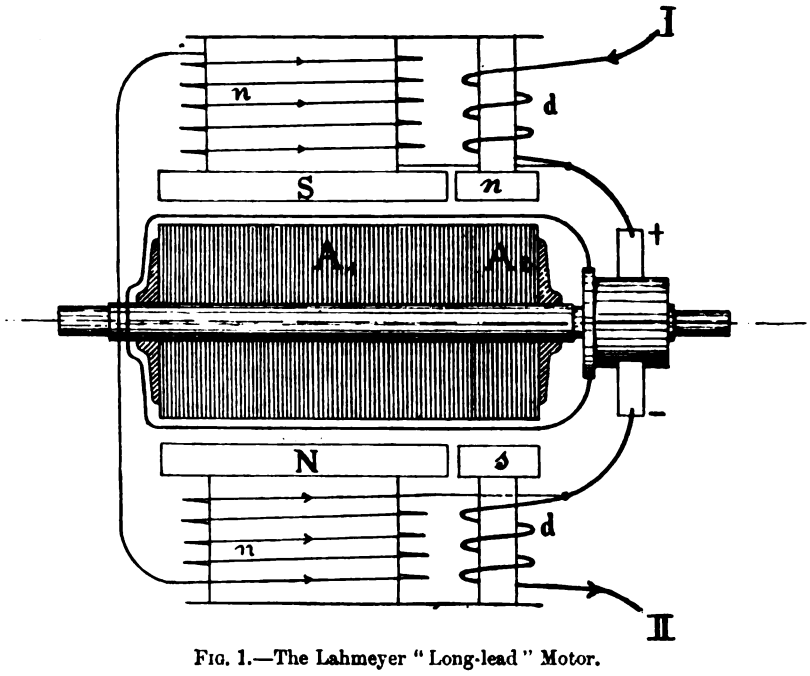

FIG. 1.—The Lahmeyer "Long-lead" Motor.

object of the transmission was to supply secondary current at Frankfort at a pressure of 110 volts. Two methods were alternately employed.

The first method involved the supply of current at a constant pressure of 2,000 volts *at* Frankfort, and to ensure this a small series-wound dynamo was circuited at Offenbach in turns. These turns are wound under the shunt coils, taken off the low-pressure commutator, and are separated from them by thick insulation. As soon as the dynamotor is started (switched on as an ordinary series motor with a liquid resistance in circuit) the low-pressure wires on the armature are the seat of an electromotive force, and current from them passes

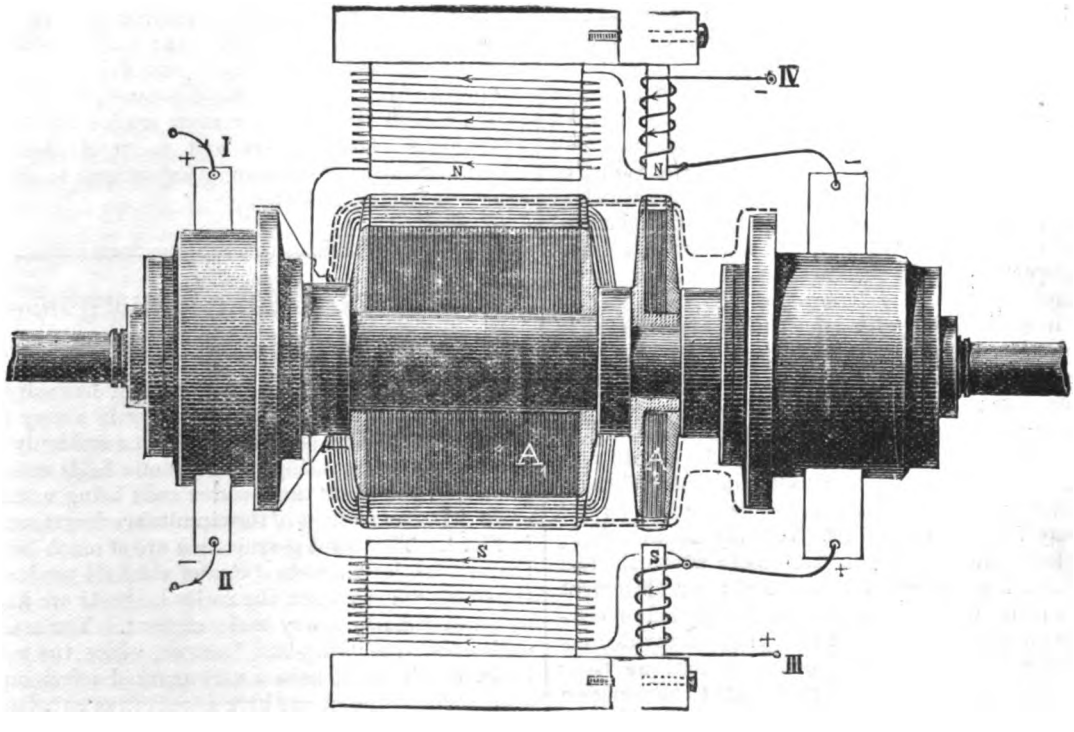

FIG. 2.—The Lahmeyer Dynamotor.

series with the primary dynamo. The result of this was that, with maximum load on the line, there was an additional 200 volts at Offenbach giving about 2,000 at Frankfort, and of course with no current the magnets of the series-wound dynamo were not excited, and there were, therefore, no additional volts. By this device, for all currents round the low-pressure coils on the magnets, and increases the magnetism induced by the high-pressure coils; these, together with the liquid resistance, are, by means of a step by step switch, then cut out of circuit. The machine is then excited by low-pressure current alone, and by a simple mechanism, which is automatically locked, while the high-

Digitized by Google

essure current is going round the magnets, the high-pressure agnet *coils* can be circuited in parallel with the low. It is ıly when the motor is to be stopped that there is a break in ıe high-pressure circuit, and an ingenious switch is used, ·ovided with a knife, which cuts through the spark at the stant of break.

the following simple way of averting this danger. Between the high and low-pressure windings there is a metallic screen, usually of copper gauze, which is divided into two parts by insulation to avoid Foucault currents, each part being joined to earth. If any high-pressure rupture occurs, the current would not pass through the metallic screen, but would go to

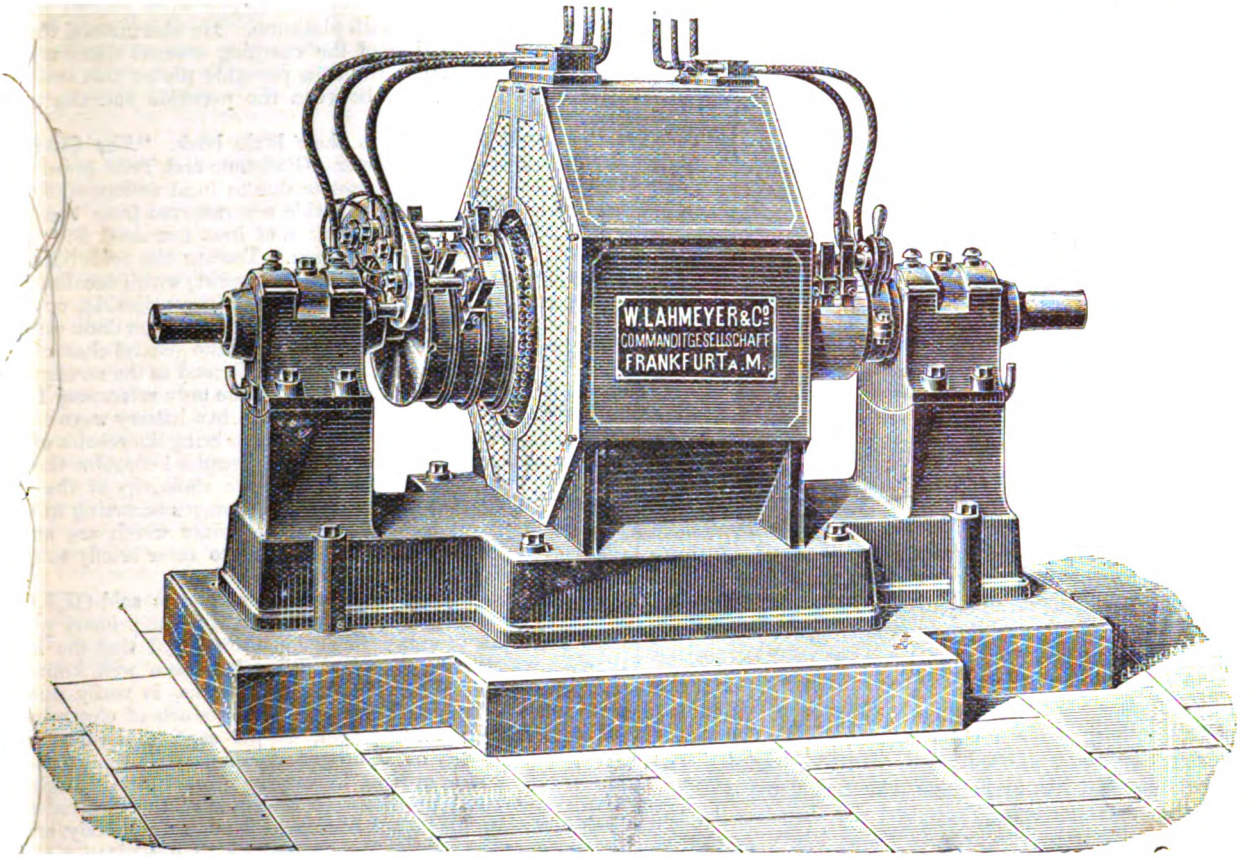

FIG. 3.—The Lahmeyer Three-Phase Dynamotor.

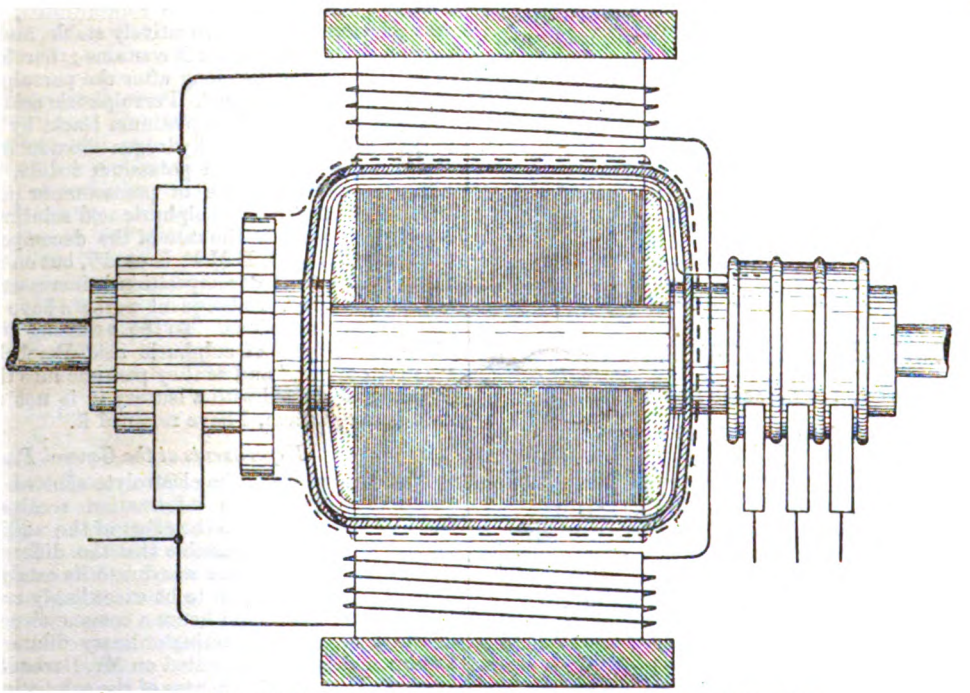

FIG. 4.—Diagram of Connections of the Lahmeyer Three-Phase Dynamotor.

It was to be feared, of course, that as the high and low-pressure wires lie one under the other on the armature, in case of a fault in the insulation the 2,000-volt current would find its way into the low-pressure wires, and so prove a danger to the users of the current. In addition to relays intended to break all contacts in such a case, Herr Lahmeyer has devised

earth. This safeguard is used by Herr Lahmeyer in his high-pressure machines whenever possible. In the dynamotor just described, it was found possible to keep the secondary pressure constant to within 4 per cent.

In the other continuous current plant, the auxiliary dynamo employed to compensate the loss of volts in the leads was

Digitized by Google

dispensed with; and the pressure at Frankfort varied from 2,000 to 1,800 volts, according to the load. The transformer used in this system has two magnetic fields, as shown in the diagram (Fig. 2). The high-pressure current supplied through brushes I. and II. is taken round the armature A_1 alone (with the exception of a few additional turns for initial excitation as before); the low-pressure coils surround the armature core A_1 in addition to the second armature core A_2. The field-magnet coils are arranged as shown in the figure, the low-pressure terminals being III. and IV. From the diagram it will be seen that the following conditions necessary for a constant secondary pressure under a varying load can be fulfilled by this system if the dimensions are properly chosen. With an increasing load the motor armature requires a small decrease in its magnetic field to keep the speed constant. The dynamo armature, on the contrary, requires a corresponding increase of field strength in order to compensate the increased loss of volts in the armature. Owing, no doubt, to the constancy of the resultant field sparking was entirely absent from the secondary commutator at change of load, and once adjusted the dynamotor required no attention. Both these machines have fulfilled the high expectations formed of them before the Exhibition.

As regards the three-phase current transmission, it was so simple and successful that a few words will suffice to describe it. In Offenbach there was a four-pole drum-armature dynamo excited by a 110-volt current. By means of rings and brushes three currents of 120deg. phase difference were taken from the armature and led by three wires to the three brushes of a corresponding machine at Frankfort. This machine (Fig. 3) needs a little description. It is, in fact, the continuous current transformer or dynamotor first described, which was supplied with a constant pressure of 2,000 volts. The high-pressure commutator was taken off, and three rings fitted on in its place, the two armature windings remaining just as before, the high-pressure coils used on the field-magnets for initial excitation being unused. (*See* diagram, Fig. 4.) The rings are connected with points on the armature 120deg. apart, and the current being supplied by brushes in the usual way, the dynamotor starts (without load), no initial excitation being needed, and as soon as synchronism is shown by the voltmeter to have been reached, the shunt windings from the low-pressure brushes are switched in and finally the lights. Between any two of the 6¼ mile conductors the mean potential difference was about 1,300 volts; but in consequence of the synchronism the pressure variations which occur from variable losses in the leads with varying loads have no effect on the constancy of the secondary 110 volts. The smooth noiseless running of this transformer of three-phase to continuous current was particularly striking. It required absolutely no attention during long runs with different loads, and there was no sparking whatever.

SECONDARY BATTERIES.

BY G. H. ROBERTSON, F.C.S., ASSOC.INST.EL.ENG.

(Concluded from page 146.)

The Chemistry of the Acid.

Although so many different modes of manufacture and preliminary treatment have been resorted to, all the batteries, so far as I am aware, which depend for their action on the couple formed between lead and lead peroxide in dilute sulphuric acid, exhibit the characteristic peculiarities noticed by Planté in his cell, namely, the high initial E.M.F. of a freshly-charged cell; the fall of E.M.F. on breaking the charging circuit, with corresponding rise on breaking the discharging circuit; the very rapid fall towards the end of discharge which occurs earlier the more rapid the discharge is, and is not due to the exhaustion of the active material, as after a rest a fresh discharge can be obtained.

As the defects, namely, sulphating and buckling, which have retarded the introduction of reversible lead batteries, are also common to the two types, it appeared possible that they were due to the same causes which produced the variations in E.M.F.; therefore, as the work of Dr. Oliver Lodge* in 1883, and of Mieslert in 1888, had shown that the causes of the variation must be sought either on the lead plate or in the acid next it, and the chemistry of the plates afforded no explanation*, I last year, with Dr. Armstrong's advice and assistance, undertook the investigations of the reactions occurring in the acid.

Planté† had considered that the peculiarities in E M F. were due to the formation of peroxides in the acid, and showed that the conditions existing in a cell were favourable to their production, since in voltameters with lead electrodes they were formed in greater quantity than in those with platinum. He also noticed that immediately on the cessation of the charging current there was often a small evolution of gas from the peroxide plate; this evolution he ascribed to local action between the peroxide and the subjacent lead.

Commenting on this in their little book, "The Chemistry of Secondary Batteries," Messrs. Gladstone and Tribe point out that the gas is oxygen, and cannot be due to local action, since the gas was evolved whether the peroxide was removed from the supporting plate or not. The application of heat increased the evolution of gas, and the gas was oxygen. Testing the acid between the plates they always found traces of something which decolourised permanganate, and might, therefore, be hydrogen dioxide, or ozone.

Although a very large amount of work has been done on the electrolysis of sulphuric acid solutions, and the general character of the change in the nature of the products formed as the strength of the solution is varied is well understood, the only references I was able to find to any examination of the acid in a battery were those just given, and therefore, I have ventured to bring the results of my own experiments before this Society, not because I consider them a final solution of the difficult problem of the chemistry of the cell, but because I hope that the study of the changes occurring in the electrolyte may help to elucidate some points which are at present obscure. And now it may be as well to refer briefly to the work which has been done in sulphuric acid.

In 1878, Berthelot‡ discovered persulphuric acid ($H_2S_2O_8$), and brought forward evidence to prove that it is the primary product of the electrolysis of sulphuric acid solutions, and that the hydrogen dioxide, which from Faraday's time has been well known to be present in sulphuric acid after electrolysis, is really due to the action of this body on the acid. The products of electrolysis vary with the strength of the acid, 40 per cent. acid (density 1,300) yielding practically no hydrogen dioxide, while below and above that strength it is present in varying proportions. High-current density and an electro-negative condition of the electrodes favour their formation.§ Persulphuric acid is an unstable body, and begins to decompose as soon as the current which has given rise to it is stopped, and its decomposition is accompanied by the formation of hydrogen dioxide, unless the sulphuric acid is too dilute. Hydrogen dioxide is also unstable when concentrated, but a weak sulphuric acid solution of it is comparatively stable, and the stability increases the less hydrogen dioxide it contains; therefore, this body is found in estimable quantities long after the persulphuric acid, which gave rise to it, has disappeared. Persulphuric acid is at once decomposed by spongy metal, such as platinum black, by heat with evolution of oxygen ||, and resembles hydrogen dioxide in these reactions, and in releasing iodine from potassium iodide, but, unlike it, has no action on permanganate of potassium or peroxide of lead. The effect of electrolysing a sulphuric acid solution of hydrogen dioxide is simply to increase the rate of the decomposition occurring spontaneously if a weak E.M.F. is used¶, but on increasing the E.M.F. though the rate of decomposition is increased, a little persulphuric acid is re-formed. Subsequent workers have in the main confirmed Berthelot's conclusions. To the oxidising oxygen in the products of the electrolysis of sulphuric acid Berthelot gave the name of "active oxygen," and as they pass one into the other, and for most purposes connected with a battery it is not necessary to discriminate between them, I have retained it.

Experiments at the General Post Office.

That the nature of the electrolyte affected the behaviour of the cell was evident from information received from Mr. Barber Starkey with respect to the effect of the addition of sodium carbonate; and it seemed possible that the different behaviour of cells containing this substance was due to its catalytic action on hydrogen dioxide, which is known to be exceedingly unstable in the presence of a trace of alkali, and hence a comparative study of the reactions occurring in cells containing ordinary dilute sulphuric acid, and in those which had been treated on Mr. Barber Starkey's plan, seemed likely to elucidate the causes of the sulphating during rest, and the high initial E.M.F., the two features most affected by his treatment.

Mr. Preece most kindly aided the investigation by allowing experiments to be carried out at the General Post Office, where one half of the secondary cells contain 1 per cent. of sodium sulphate, and the other half ordinary dilute acid, density 1,180. He also put at my disposal the records of the behaviour of the cells, and they proved that there was much less sulphating with sodium sulphate, as shown by the density of the acid never falling to the same extent as in the plain cells.

The following readings, taken from short-circuited cells with badly broken plates, illustrate this. In two cells containing ordinary dilute acid the density of the electrolyte had fallen to 1,100, while according to the last readings before the short-circuit occurred it had been 1,170 and 1,180 respectively; while in two sodium sulphate cells the density had only fallen to 1,180 from 1,200 under similar circumstances.

This was strong evidence in favour of the hydrogen dioxide formed in the working of the cell being appreciable in quantity, since if sulphating were only due to local action between the support and the paste there does not appear any reason why the addition of sodium sulphate should affect it.

Whenever the cells were tested they were always found to contain "active oxygen," which was due to the presence of persulphuric acid and peroxide of hydrogen in varying proportions. During charge persulphuric acid is the main constituent; during discharge the quantity of hydrogen dioxide gradually increases; while in a cell which has been at rest some time there is very little except hydrogen dioxide to be found.

In addition to the tests made on the cells in the electric light and telegraph batteries, I studied the formation of the "active oxygen" during charge and discharge on some cells which were kindly set apart for my special use. The "active oxygen" forms at once on the passage of the current, decreases slightly, and then increases to a little above its first value. Starting either charge or discharge always causes an initial increase, except in the case of cells which have been long idle; then there is a diminution due to the decomposition of the excess of hydrogen dioxide in the acid.

In the sodium sulphate cells the amount of the oxidising agent was usually less than in the plain cells; and the amount of hydrogen dioxide was always so unless the battery had been at rest for some time, when the conditions were occasionally found to be reversed. This, I suppose, is due to the proportion of "active oxygen" in the form of hydrogen dioxide at the moment of stopping the current being greater in the plain than in the sodium sulphate cells, while the latter contain more persulphuric acid. In both cells the hydrogen dioxide present at the time of stopping the current will be reduced on the plates, sulphating the surface, and more or less screening them from further action; but as the sodium sulphate cell contains more persulphuric acid, the subsequent formation of hydrogen dioxide will be greater in it than in the plain cell. As far as I could discover sodium sulphate has little or no action on the acid unless it is added during the electrolysis, or to acid which has just been taken from a cell through which a current is passing.

The Pink Colour o the Acid.

It has often been noticed, that during charge, particularly with new cells, a pink colour starts from the peroxide plates, and gradually spreads over towards the lead plates, fading away, however, before reaching them. This pink colour was referred to by Mr. Crompton at a meeting of the Institute of Electrical Engineers on December 13, 1890, and its origin gave rise to some discussion; so as the acid in many of the cells at the Post Office was pink, I tested it by concentrating it down, neutralising with sodium carbonate, and then igniting on platinum foil, and always got the characteristic green of manganese.

However, lest the manganese should have come from some other source than the pink acid, I compared the absorption spectrum of the acid with that of a solution of potassium permanganate of the same shade of pink, and found they both gave the characteristic bands in the green (Fig. 14). I also found that using two strips of platinum as electrodes in a solution of manganous sulphate, or any two strips of lead in dilute acid, gave the same colour and the same absorption bands, provided the electrodes were sufficiently far apart

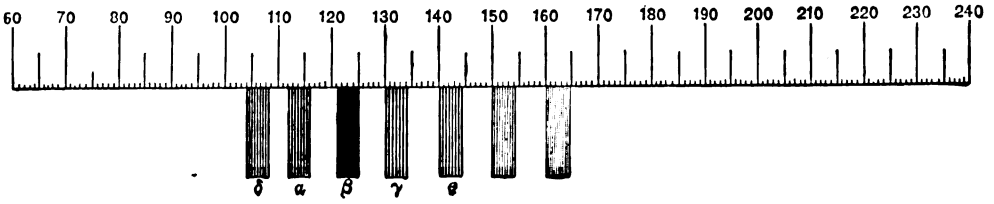

FIG. 14.—Absorption Spectrum of Potassium Permanganate.

To test whether electrolysed acid was able to reduce pure peroxide of lead, two equal lots of peroxide were taken by weighing one against the other, and put in two flasks. On to each 100 c.c. of acid from next the positive plate of a cell at full charge was poured, and this caused the evolution of oxygen, which continued slowly for some days. At the end of a fortnight the amount of peroxide of lead in each sample was estimated, and it was found to have decreased from 97·4 per cent. to 93·94 per cent. and 94·04 per cent. respectively.

This appears to explain the well-known deleterious effect of rest on a cell; for although persulphuric acid itself does not reduce peroxide of lead, it forms hydrogen dioxide on standing, which is capable either of oxidising the lead plate to litharge, or of reducing the peroxide plate to the same substance. In each case the litharge is converted into sulphate by the sulphuric acid.

In an ordinary cell in good order the amount of "active oxygen" is small, varying in quantity from about 0·01 grm. to 0·02 grm. per litre; but this means that in a 45-pint cell (the size used at the Post Office) there was always sufficient to convert from 3·25 grms. to 7·5 grms. of peroxide of lead into sulphate, or to undo the work of one to two ampere-hours charge.

This is not a serious matter if the cells are kept working, as the peroxides are being continually broken up with each reversal of the current; but if the cells stand idle the plates get sulphated, and the amount of "active oxygen" formed in the next passage of the current shows a marked increase.

The figures just given do not represent the total amount of "active oxygen," since the acid absorbed by the plates cannot be tested; but as the acid has more oxidising power the nearer you get to whichever is the positive plate, except at the commencement of discharge, and the total quantity of "active oxygen" increases rapidly soon after breaking circuit, it seems fair to assume that this increase is due to diffusion from the plates of acid, which has more oxidising power than that in the body of the cell.

This increase is followed by a decrease which is rapid at first, and then gradually gets very slow, and practically ceases while there is still a fair proportion of "active oxygen" left in the cell.

to prevent reduction by the hydrogen evolved from the negative. This result was important, for it is well known that the pink colour disappears from the acid in a short time if it is taken from the cell, and as persulphuric acid has no action on permanganate, but hydrogen dioxide decolourises it, this disappearance of the colour shows that the latter is formed.

The Effect of Hydrogen Dioxide on the E.M.F. of a Cell.

The presence of hydrogen dioxide having been thus proved, both directly and indirectly, its effect on the E.M.F. of the cell was tested. This was done by using strips of lead packed tight into small porous pots, with peroxide of lead to represent the peroxide plates, and using plain strips as the lead plates. A solution of pure sulphuric acid, density 1,180, was used as the electrolyte. The E.M.F. of the couple was taken by the deflection method, and then a drop or two of hydrogen dioxide was added to the acid, which produced a great diminution, or even reversal of the E M.F.

The effect of introducing hydrogen dioxide into the body of the peroxide paste was also tried, with a view of reproducing, if possible, the conditions of a cell which is started discharging directly the charge is completed, and in which the "active oxygen" would be accumulated at the positive plate, leaving the lead plate free, and I found that there was a slight increase in E.M.F.

Thus the variations in E.M.F. appear to depend on which plate hydrogen dioxide is formed at. When present at the peroxide plate it causes a rise, but when diffused through the acid and present at the lead plate, it causes a lowering of the E.M.F.; and the rise in E.M.F., sometimes noticed on starting the discharge of a cell which has been at rest (mentioned in Prof. Ayrton's Paper, *Journal Institution Electrical Engineers*, 1890, p. 572), is probably due to the electrolysis and decomposition of hydrogen dioxide; for in a cell which has been long idle, practically the whole of the "active oxygen" is due to this body.

Conclusions.

From the same faults appearing in batteries of such different construction, and judging also from the results of the experiments

Digitized by Google

recorded in this Paper, it would appear that the troubles occurring in batteries are due rather to causes arising in the working than in the manufacture. What is required is some substance which can be added to the acid to check the formation of the oxidised bodies in it which cause sulphating, without at the same time injuring the plates in other ways.

Nearly all the "forming" baths which have been introduced are baths in which hydrogen dioxide would be broken up as soon as formed, and perhaps in some modification of them the electrolyte of the future will be found; though, since the products of the electrolysis of sulphuric acid vary with the strength of the acid, and the current density, no hard and fast rule can be laid down for the treatment of cells.

In cells containing acid below density 1,200, in which the proportion of "active oxygen" existing as hydrogen dioxide is high, the addition of 1 per cent. of sodium sulphate, or similar substance, is likely to prove beneficial, particularly if the work of the cells is intermittent. As the strength of the acid is increased, however, and the conditions are more favourable to the stability of persulphuric acid, less hydrogen dioxide will be produced, and there is more chance of the alkali released from the sodium sulphate during electrolysis damaging the plates.

Also, Dr. Marshall has succeeded in preparing pure persulphuric acid, and has shown this year that it forms salts with the alkalis, which are very stable; and what the effect on a cell of the formation of sodium persulphate in it would be, is quite unknown. Although the formation of peroxides in the acid does not apparently account for the great gassing and sudden loss of charge sometimes observed, still we have seen that makers are reverting to Planté's process of manufacture, or modifications of it, and we may find that in this case also he was right, and that it is to the electrolyte we must look if we wish to find the means of materially improving the lead reversible battery.

In conclusion, I must thank the firms who have assisted me in the compilation of this Paper by supplying information in response to circulars sent out.

PHYSICAL SOCIETY.

At the meeting of the Physical Society on December 4th, the following Papers were read :—

'A Permanent Magnetic Field,"

by W. HIBBERT. The author had noticed the approximate constancy of an "aged" bar magnet, and he obtained still greater constancy by attaching pole pieces to a bar magnet of such a shape as to give a nearly closed circuit of small "magnetic resistance." The pattern now described consists of a steel rod, 1in. diameter, and about 2½in. long, with a cast-iron disc, 4in. diameter, and ⅝in. thick, fixed at one end; the other end is fitted in a hemispherical iron shell, which surrounds the bar and comes flush with the upper surface of the disc. An annular air space, less than $\frac{1}{16}$in. wide, is left between the cylindrical surface of the disc and the inside of the shell, and when the bar is magnetised, a strong magnetic field exists in this space. To use this field for producing electromagnetic impulses, a coil of wire is wound in a shallow groove on a brass tube which can slide easily through the annular space, thus cutting all the lines. The tube is allowed to fall by its own weight, a neat trigger arrangement being provided for effecting its release.

The instrument exhibited had 90 turns of wire in the coil, and the total magnetic flux across the air space was about 30,000 C.G.S. lines. A large electro-magnetic impulse is therefore obtainable, even through resistances as great as 10,000 ohms Tests of three instruments show that there has been practically no magnetic decay in seven months. The author, therefore, considers them satisfactory, and is prepared to supply them as magnetic standards. To facilitate calculation, the number of lines will be adjusted to a convenient number, say 20,000 or 25,000.

Several uses to which the instruments are well suited are mentioned in the Paper, and a simple way of determining permeability by the magnetometer method is described.

DISCUSSION.

Mr. BLAKESLEY thought the name given to the instrument was inappropriate, for it really gave a constant impulsive E.M.F.

Dr. SUMPNER said the constancy of the sensibility of d'Arsonval galvanometers was a measure of the constancy of magnets having nearly closed circuits. Such instruments in use at the Central Institution had remained unchanged for several years.

Prof. S. P. THOMPSON admired Mr. Hibbert's instrument, and thought it would be very useful in laboratories. Standard cells, he said, were not always reliable, and condensers were the most unsatisfactory of electrical standards. On the subject of permanency of magnets, he said that Strouhal and Barus found that magnets with nearly closed circuits were most constant, and that to give the best results, the hardness of the steel should be less the more closed the circuit. Mr. Hookham had also found that by using a nearly closed circuit, and reducing the strong magnetisation by about 10 per cent., great constancy cou'd be obtained. Some years ago he (Dr. Thompson) had tried the effect of illtreatment on magnets, and observed that touching or hitting a magnet with non-magnetic material had little effect, whilst similar treatment with iron or magnets affected them considerably. Suddenly removing the keeper of a magnet tended to increase the magnetism, whilst putting a keeper on suddenly had the reverse effect. Strouhal and Barus had also investigated the temperature coefficient of magnets, and found that this might be reduced by subjecting the magnet to rapid changes of temperature after the first magnetisation, and then remagnetising.

Mr. W. WATSON inquired what was the percentage fall in strength of Mr. Hibbert's magnets. The bars used in magnetic surveys had been tested frequently, and they lost about 0·5 per cent. in six months.

The PRESIDENT (Prof. Ayrton) asked what was the temperature coefficients of the magnets described in the Paper. Mr. Evershed, he said, thought it was between 0·01 per cent. and 0·05 per cent. for ordinary magnets. He thought the instrument shown by Mr. Hibbert would be of immense value if the magnet was really permanent. By it ballistic galvanometers could be readily calibrated, and, when combined with a resistance box, it could also be used as a standard for current; for since the constant of a ballistic galvanometer for quantity can be determined from its constant for current, if the periodic time be known, conversely that for current can be found from the constant for quantity. In some instances this would be of great use Speaking of the temperature coefficient of condensers, he said that in some cases the specific inductive capacity of dielectrics diminished with rise of temperature whilst in others it increased.

Mr. HIBBERT, in reply, said he found the temperature coefficient of his magnets to be, roughly, about 0·03 per cent., but he had not investigated the matter very carefully. In making his measurements, no correction had been made for the variation of capacity of his condenser with temperature.

'Note on Rotatory Currents,"

by Prof. W. E. AYRTON, F.R.S. The subject, the author said, was probably familiar to most persons present, for it had been frequently referred to in the scientific papers. Alternate currents could be obtained from an ordinary direct-current dynamo by making contact with two points in the armature say by connecting these points to insulated rings on the shaft, and using extra brushes. A direct-current motor similarly treated transforms direct currents into alternating currents, or into mechanical power. If two pairs of points in the armature be selected, situated at opposite ends of two mutually perpendicular diameters, then two alternating currents differing in phase by 90deg. can be obtained; and by choosing suitable points in the armature, two, three, or more currents differing in phase by any desired angles can be produced. In ordinary motors the connection for doing this would be troublesome; but the Ayrton and Perry form, which has a stationary armature, lends itself readily to this purpose, for contact can be made with any part of the armature with great facility. A motor of this kind was exhibited, in which contact was made with four equidistant points on the armature. On connecting opposite points through fine platinum wires, and running the motor slowly, the wires glowed alternately, one being bright whilst the other was dark, and *vice versâ*, thus demonstrating the existence of two currents in quadrature. When the four points on the armature were joined to the four corners of a square of platinum wire, the wires became incandescent in succession, the glow appearing to travel round the square and suggesting the idea of rotatory currents. A Tesla alternating-current motor was also driven by two currents differing in phase by 90deg. obtained from the armature of the Ayrton and Perry direct-current motor above mentioned.

The case with which currents differing in phase by any amount can be obtained from such a motor, led the author to investigate theoretically the case of two circuits connecting opposite ends of two diameters inclined at any angle. Calling the currents in these circuits at any instant, A_1 and A_2, he had found that

$$A_1 = 2n E_0 \frac{\sqrt{\left(r_2+\rho\frac{\pi}{2}\right)^2+\rho^2\left(\frac{\pi}{2}-\alpha\right)^2-2\left(r_2+\rho\frac{\pi}{2}\right)\rho\left(\frac{\pi}{2}-\alpha\right)\cos\alpha}}{\left(r_1+\rho\frac{\pi}{2}\right)\left(r_2+\rho\frac{\pi}{2}\right)-\rho^2\left(\frac{\pi}{2}-\alpha\right)^2}\sin(pt+\phi).$$

where

E_0 = maximum E.M.F. per convolution,
n = number of turns on armature per radian,
ρ = resistance of armature per radian,
p = angular velocity of rotation,
r_1 = resistance of external circuit in which current A_1 passes,
r_2 = resistance of external circuit in which current A_2 passes, and

$$\tan\phi = \frac{\rho\left(\frac{\pi}{2}-\alpha\right)\sin\alpha}{r_2+\rho\frac{\pi}{2}-\rho\left(\frac{\pi}{2}-\alpha\right)\cos\alpha}.$$

A similar expression in which r_1 is written for r_2, and r_2 for r_1, gives the value of A_2.

Digitized by Google

The phase angle between the currents A_1 and A_2 is given by

$$\tan(\phi+\psi)=\frac{\left(r_1+\rho\frac{\pi}{2}\right)\left(r_2+\rho\frac{\pi}{2}\right)-\rho^2\left(\frac{\pi}{2}-\alpha\right)^2}{\left(r_1+\rho\frac{\pi}{2}\right)\left(r_2+\rho\frac{\pi}{2}\right)+\rho^2\left(\frac{\pi}{2}-\alpha\right)^2-\frac{\rho\left(\frac{\pi}{2}-\alpha\right)\left(r_1+\rho\frac{\pi}{2}\right)}{\cos\alpha}}\tan\alpha.$$

The expression for ϕ shows that the phase of the current in circuit A_1 is independent of the resistance r_1. On the other hand, varying r_2 alters ϕ. It was also pointed out that tan $(\phi+\psi)$ is generally greater than tan α.

Prof. J. PERRY, F.R.S., read a Paper on "Struts and Tie rods Laterally Loaded."

LEGAL INTELLIGENCE.

Brunton v. Electrical Engineering Corporation.

In the Chancery Division of the High Court of Justice, on Friday, the case of Brunton *v.* Electrical Engineering Company came before Mr. Justice Kekewich in the form of a summons, raising the question whether Mr. Holt had a lien on the books, leases, and papers which, by the direction of his Lordship, he had handed over to the receiver and manager of the Company.

Mr. BRAMWELL DAVIS (with whom was Mr. Renshaw, Q.C.), on behalf of Mr. Holt, said his client claimed a lien on the papers, &c., in respect of costs for work done before the liquidation of the Company. It appeared that in January, 1890, Messrs. Statter and the United Electrical Engineering Company were amalgamated, and called the Electrical Engineering Corporation. Prior to the amalgamation Mr Holt acted for Messrs. Statter, and Messrs. Dowson and Co. were solicitors for the United Company. After the amalgamation Mr. Holt and Messrs. Dowson and Co. were solicitors for the Corporation. A receiver was appointed in March last, and a resolution to wind up the concern was passed on April 23rd. The documents which Mr. Holt had in his possession were the title deeds of freehold and leasehold property, and of the patents purchased. He (the learned counsel) submitted that as solicitor Mr. Holt had a lien on the documents in respect of his costs, and that, therefore, he was entitled to have his costs out of the £270 paid into Court pending the result of the summons.

Mr. WARMINGTON, Q.C., and Mr. SWINFORD EADY opposed the summons, and argued that Mr. Holt had no lien upon the documents.

His LORDSHIP held that Mr. Holt had a lien, and directed that he should have his costs out of the sum which had been paid into Court.

Edison-Swan United Electric Light Company v. Hamilton and Roxburgh.

In the Chancery Division of the High Court of Justice, on Saturday, the case of the Edison-Swan United Electric Light Company *v.* Hamilton and Roxburgh came before Mr. Justice Mathew (sitting for Mr. Justice Stirling). This was an action brought by the plaintiff company against the defendants, Messrs. Hamilton and Roxburgh, of 4B, Newland-terrace, Kensington, for an injunction restraining them from infringing their (plaintiffs') patents and for damages. The defendants did not appear to defend the case, although by their pleadings they had denied the alleged infringement.

Mr. BREMNER opened the case for the plaintiffs, and said the validity of the patents had been upheld in the Court of Appeal. The sole question was one of infringement.

Mr. JOHN MYLES MOFFATT, engineer in the employ of the Edison-Swan United Electric Light Company, stated that on the 4th of May he went to the defendants' shop, No. 4, Newland-terrace, Kensington, and purchased four electric incandescent lamps. On June 3rd he purchased 20 more lamps. He handed the lamps to Mr. Gover, assistant secretary to the plaintiffs' company.

Mr. HENRY CHAS. GOVER, assistant secretary to the Edison Swan Company, stated that he handed the lamps which he received from the previous witness to Dr. Fleming, electrician to the Company.

Dr. J. A. FLEMING stated that he had devoted great attention to electric lighting during the past 14 or 15 years. He had carefully examined the lamps which he received from Mr. Gover. They were composed of a glass reservoir from which the air had been exhausted, and through the walls of the glass reservoir platinum leading wires were sealed in, and to the ends of these wires was attached a filament which upon experiment he found to be carbon. He was well acquainted with the Edison patent, and, in his opinion, the lamps he examined infringed that patent—they contained the four elements of Edison's second lamp. He was also well acquainted with the Cheesbrough patent, which was a special process for testing the filament. The filaments of the lamp he examined had been treated by the Cheesbrough process. He knew the lamps made by the Edison Company, but the lamps produced were not made by that Company.

His LORDSHIP: I think that is enough. You ask, Mr. Bremner, for an injunction restraining the defendants from making any more of these lamps.

Mr. BREMNER: Yes, and for an order for delivery up of all lamps infringing the patent.

His LORDSHIP: Yes; you are entitled to that. You are entitled to an injunction restraining the defendants from further infringement, and for an order for the delivery up of all infringing lamps, and costs.

Mr. BREMNER: I also ask, under Section 29 of the Patents Act, for a certificate that we have proved our breaches.

His LORDSHIP: Yes.

Mr. BREMNER: And under Section 30 of the Act, the validity of the patent having previously been upheld, we are entitled to costs as between solicitor and client.

His LORDSHIP: I don't order them; but if the statute gives them to you, well and good.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *December* 5, 1891.

Storage Battery Traction.—A characteristic contribution to the history of storage battery traction comes from the city of Dubuque, Iowa. Two trolley systems were already in operation there when the owners of the only other road in town, which had the marked advantage of a level track, determined to use the storage battery. The route was put in operation during the early part of this year, and at first glowing reports of remarkable success came from it. The outlook continued to be propitious until quite recently, when the Accumulator Company of Philadelphia which furnished the batteries, filed a short time since a suit in the United States courts against the Dubuque Street Railway Company for nearly $50,000; they also, to make assurance doubly sure, filed a similar suit in the Dubuque District Court for the same amount. These actions were to recover payment for the storage batteries used. The defence put in is the old, old story of worthless guarantees; instead of each battery running a year at a cost for renewals of not over $2.50, the Dubuque Company was compelled to renew them every 30, 60 or 90 days. Up to date the expenditure upon them has been 10 times the figure given, and besides that it has been necessary to increase the number of cells per car from 50 to 80. It certainly would seem that however much allowance might be made for *ex parte* evidence the storage battery has been up to its old tricks again, tricks that became familiar in New York several years ago. In the abstract the storage battery is looked upon with favour as furnishing a very pretty solution of the electric traction problem; in the concrete the cost of repairs rises to forbidding magnitude. All this does not deter continued efforts being made; a company with half a million of dollars capital, backed by responsible business men, has recently been organised in New York, for the purpose of developing storage battery traction; and in addition experiments have been instituted in Fort Wayne, Indiana, looking to a new adaptation of the alkaline zincate form of battery for street car work. This latter is under the auspices Mr. M. M. M. Slattery, who has worked over that type of battery for several years and claims to have been one of the first experimenters with it. Between the Waddell-Entz combination and Mr. Slattery this particular form of battery ought to be worked for all there is in it before long.

Government Control of the Telegraph.—Last evening a most interesting discussion was held at the New York Electric Club. The Paper of the evening was on Government Control of Telegraphs, and was read by Mr. E. Rosewater of Omaha, Nebraska. He is a vigorous advocate of Government monopoly; the interests of the members of the Electric Club lie for the most in the opposite direction, and consequently a vigorous discussion ensued, with the usual result,—that is leaving the subject in about its former state. There is a strong feeling in this country that so great an increase of Government patronage would be, under the political conditions at present existing, a source of increased official corruption

City of London Electric Lighting Company.—We are informed that this Company has appointed Mr. David Cook, late Superintending and Consulting Electrical Engineer to the Corporation of Glasgow, as general manager. The supply of current by this Company to private consumers was commenced on Monday last from the Company's central station at Meredith's Wharf. The Mansion House is being supplied with light throughout; and the Company is now prepared to connect consumers on both sides of Queen Victoria-street (eastern end), and expects to be able to connect those in the western end of Queen Victoria-street early in 1892.

PARIS NOTES.

(FROM OUR OWN CORRESPONDENT.)

PARIS, *December* 15, 1891.

The new electrical journal, *L'Industrie Électrique*, has now been definitely set on its legs, and the first number will appear on January 1, 1892. *L'Industrie Électrique* has been founded by some thirty persons interested in the electrical industry, who felt the necessity for a serious electrical journal which should keep French electricians *au courant* with what was going on abroad and at home. M. Hospitalier is to be the editor of this new journalistic venture, and he will have the able assistance of M. Gaston Roux. Accuracy and impartiality will, therefore, it may be anticipated, be prominent characteristics of this journal. *L'Industrie Électrique* will differ from the old *Électricien*, over which M. Hospitalier presided so admirably, in being of much the same size and shape as its English contemporaries; it will consequently be in a position to devote ample space to important Papers, and to deal with a variety of subjects in a single issue. It goes without saying that serious obstacles had to be overcome before *L'Industrie Électrique* was definitely inaugurated.

MM. Julien, of Brussels, have taken over the Société Française des Accumulateurs Électriques (E.P.S.) in order to energetically push the sale of accumulators in Paris. This announcement has frequently been made before, but hitherto without much foundation, since the agreement between the two concerns was only signed last week. The action brought against M. Paul Gadot by the Société Française des Accumulateurs came on for hearing on Thursday last. After a few formal proceedings the case was adjourned to January 21st.

M. M. J. J. Heilmann, the inventor of an electrical system of railway working, briefly alluded to in these columns some little time since (see *The Electrician*, Vol. XXVI., p. 586), has succeeded in forming a company with a capital of £12,000 for the purpose of putting his ideas to a practical test. The first electric locomotive on M. Heilmann's system will be at work early in January. The motors, which are placed direct on axles, are of the "polyphase" genus, so that the difficulties inevitable with commutators and brushes are avoided. On the other hand, the firm of Bréguet have just completed an accumulator locomotive for the Chemin de Fer du Nord.

CORRESPONDENCE.

PLATINOID *v.* COPPER FOR D'ARSONVAL GALVANOMETERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As I am responsible for the statement that copper winding makes a given galvanometer 25 times more sensitive than platinoid winding—see extract of discussion, Institution of Electrical Engineers (*The Electrician*, p. 127, 4th inst.)—perhaps you will kindly allow me to make a few remarks to Mr. Mather's interesting contribution on the subject in your last issue.

Mr. Mather opens his argument with the following words: "Although copper has important advantages, where the instrument is only required to measure the *current* passing through it, its large temperature coefficient . . . . &c."

It is shown in the Paper by Captain Sankey and the writer that the two galvanometers belonging to the set of instruments in question must be suitable for a number of measurements, where it is essential that the galvanometer current is small and the resistance fairly low, *e.g.* to calibrate by means of a Clark cell, which frequently has about 1,000 ohms resistance, to measure all kinds of resistances, &c. In order that the platinoid winding shall be suitable for such purposes the d'Arsonval galvanometers must be made at least 20 times as sensitive as those at Thames Ditton, whilst with copper winding these are found sensitive enough for all-round use.

I understood Prof. Ayrton to say that Mr. Mather's improvements had led to increased sensitiveness far beyond the above ratio, and then, in such instruments, of course, platinoid winding is the best. But when Mr. Mather in his letter shows that *with the given instruments* platinoid winding should have been used, then I am afraid he goes too far; for not only would the 10-ohm platinoid coil, which he proposes, be useless for the special purposes referred to, but even for measuring the potential difference at the terminals of the ampere-rheostat it would be a very doubtful improvement, as the following consideration will show.

Mr. Mather says:—"Let no alteration whatever be made in the platinoid sheet used at Thames Ditton to carry the main current, but let the 430-ohm copper coil of the d'Arsonval galvanometer used to measure the potential difference at the terminals of this sheet be replaced by a 10-ohm platinoid coil, the price of which would, of course, be less; then the deflection for a given current passing through the sheet will be increased 25 per cent., and the temperature coefficient reduced to $\frac{1}{15}$th of its value for the copper coil."

It appears that Mr. Mather allows 10 ohms resistance for the suspension; the two coils then compare as follows:—

Current in copper coil for maximum deflection = 66 micro-amperes
,, platinoid coil ,, ,, = 430/20 × 66 = 1,419 ,,
Number of turns in copper coil = N_c
,, ,, ,, platinoid coil = $N_p = 5/4 \times 20/430 N_c = 1/17{\cdot}2N$

Further, as a turn has the same length in either coil and as the ratio of the resistances of the two coils is 42 and the ratio of the specific resistances of the two metals is 25, we shall have:

Cross-section of copper wire = s_c
,, platinoid ,, = $s_p = 1/17{\cdot}2 \times 42 \times 25\, s_c = 61 s_c$
∴ Bulk of metal in copper coil = b_c
,, ,, ,, platinoid ,, = $b_p = 61/17{\cdot}2\, b_c = 3\frac{1}{2}\, b_c$

The platinoid coil thus introduces the following:—

Advantages.	*Disadvantages.*
1. It is (according to Mr. Mather) cheaper than the copper coil.	1. An extra galvanometer must be installed for calibrating and testing work.
2. Twenty-five per cent. increase in the deflection for currents *up to* 30 *amperes*.	2. Twenty-one and a-half times more galvanometer-current than with copper coil, 462 times more heat in each resistance-coil placed in series with galvanometer to measure currents above 30 amperes, errors due to this cause.
	3. Excessive weight of coil.

Finally, as to the temperature coefficient:—This is with the platinoid coil about ·023 per cent. per °C., with the copper coil for currents over 200 amperes (about 8,600 ohms in platinoid coils in series with galvanometer) ·04 per cent. and for currents over 500 amperes (about 17,700 ohms in series) ·0314 per cent.—I am, &c., F. V. ANDERSEN.

December 14, 1891.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Mather in the extreme case he takes, though he debits me (I don't know why) with hanging a ·4-ohm coil with a 10-ohm suspension, forgets that he must credit me with the fact that such 10-ohms suspension is it self-platinoid, so that to stand on the same footing with his 20-ohms total platinoid there would be, with the internal resistance of 9·6-ohm, 49 platinoid to 1 of copper, or a still lower temperature coefficient than I claimed before. If I wanted to employ a ·4-ohm coil I should certainly use the low-resistance suspension, for which, I believe, we have originally to thank Mr. Mather himself and Prof. Ayrton; indeed, my firm is now using them for higher coils as well. To return to the main point: the fact remains that the increased error due to the copper winding *is* only $\frac{1}{80}$ per cent. per degree. Mr. Mather's way of putting it, viz., that the temperature coefficient is 50 per cent. higher only amounts to this—that if he can afford to ignore 3 degrees difference of temperature I can only ignore 2 degrees.—I am, &c., C. W. S. CRAWLEY.

P.S. I see that in Capt. Sankey's Paper the temperature coefficient of his platinoid strips comes out only about ·021.

THE VALUE OF THE "EXTRA CURRENT" ON BREAKING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Allow me to call attention to a point in Dr. Fleming's book, "The Alternate Current Transformer," which seems to me to require some explanation. It is, perhaps, rather late

Digitized by Google

in the day to raise the question; but as it has, I believe, not yet been discussed, I may perhaps be excused for my delay.

On page 190, while discussing the effect of self-induction at breaking a circuit, Dr. Fleming writes as follows:—"This extra current may have at a particular instant a higher value than that of the strength of the steady current, so that for a short instant the primary current may be actually increased on beginning to break the circuit before it commences to decay." This sentence is apparently founded on the results of some experiments by Blaserna described on pages 196-201. The particular case of the extra current at breaking is described on pages 199 and 200, and on page 201 is a sketch of the curve obtained from this experiment. Here we actually see the current rising above its steady value before it begins to die away. Now surely this extraordinary result must have been produced by some experimental error, for which due correction has not been made. It seems to me pretty obvious that self-induction cannot have caused the current to rise above its steady value, but it may be strictly demonstrated as follows:—

Let E be a constant E.M.F. acting in a circuit of resistance R and inductance L. At a certain time t, after the moment of beginning to break the circuit, let the current be i, and the resistance $R+r$, where r is the resistance of the spark at the break. Let I represent the steady current before breaking,

then $$E - L\frac{di}{dt} = i(R+r),$$

and $$E = IR,$$

subtracting $$-L\frac{di}{dt} = ir - R(I-i).$$

Now if the current i ever rises above the value I, the right-hand side of this equation must be positive and $\frac{di}{dt}$ negative. But it is quite evident that if the current is never rising it can never get higher than I.

It is, of course, impossible to suggest an explanation without a description of the method of interpreting the results of the experiment; but does it not seem possible that the self-induction of the galvanometer (pages 199 and 200) may have interfered with the results?—I am, &c., A. E. Levin.

Plattenstrasse 44, Zürich,
December 5, 1891.

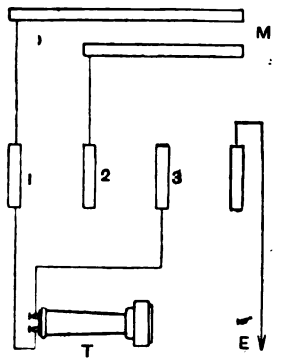
TO THE EDITOR OF THE ELECTRICIAN.

Sir: In brief reply to his criticism on a paragraph and figure in my book on the "Alternate Current Transformer," I beg to thank Mr. Levin for pointing out what is more an ambiguity than an error in one case, but clearly an error in the other. It would require more time than I have at my disposal at this moment to reply fully to Mr. Levin's reasoning in the latter half of his letter; but as regards the paragraph on page 190, a further expansion is evidently necessary to avoid conveying an erroneous notion. This I shall hope to give. With regard to the figure 18 on page 201, this has no essential connection with the former paragraph on page 190, neither does it represent the actual plotting of observations, but was only intended in a very rough way to represent the nature of the oscillations at the commencement and end of the period. The curve at the end ought not, as far as I know, to rise up as it does, but to begin to fall at once. This should, therefore, receive correction, and I am indebted to Mr. Levin for calling attention to it. I may just, however, point out to Mr. Levin that his reasoning in the latter half of his letter would, if correct, not only forbid any rise in the current strength at break, but fail to indicate the possibility of the existence of oscillations at all under any circumstances. These essentially depend upon the existence of capacity somewhere in the circuit, and this is not acknowledged in his equation.—I am, &c., J. A. Fleming.

ON THE TELEPHONING OF GREAT CITIES.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: On reading Mr. A. R. Bennett's Paper before the British Association under this title (p. 476, Vol. XXVII., of *The Electrician*) I was struck with the circumstance that it does not appear to have been noticed that the switch shown on page 476 is capable of being considerably simplified. Instead of the nine contacts therein used four only are necessary. If, for instance, the four contacts of the upper row are used, as shown in the accompanying sketch, all that is required is to connect the two conductors (M) to the first two contacts (1 and 2); 4 is connected to earth, and the telephone (T) is placed between 1 and 3. When not in use the telephone switch must then connect 2 and 3, whilst when in use 1 is connected to 2, and 3 to 4.



In the discussion it was further stated that in the Mann system an important improvement had been made by Mr. J. D. Miller in the connections of the so-called service wires. According to the sketches published, these service wires constitute a closed metallic circuit. From this a wire is carried through the apparatus in the exchange to earth, and in every subscriber's room is a terminal of the service wire to which his instrument can be connected when he wishes to call up the exchange. Mr. Miller inquires if such an arrangement, which he arrived at "early in 1887," and which was first applied in Dundee in 1888, had been previously known. I may inform him that in my "Katechisung der Elektrischen Telegraphie," in 1872 and 1882 (fifth edition, p. 265; sixth edition, p. 395), I had briefly described this method for fire alarm work.

An equivalent arrangement, differing only in the use of the earth-line, was patented in Germany on April 25, 1885, by Lewis H. McCullough, and I therefore took occasion to publish in the *Elektrotechnishe Zeitschrift* for 1886, p. 224, a full description of my method, which had then been long well-known, and to make it clear with figures. Mr. Miller explained that he had no knowledge of the previous existence of any such arrangement. He had therefore re-discovered it, and applied it to the service wire in the Mann system. Consequently, he followed the same path as I did myself; for the older arrangement of the service wire in the Mann system mentioned by Mr. Bennett, from which Mr. Miller started, is the equivalent of that so often used for fire alarms (described by me in the *Elektrotechnische Zeitschrift*), and long since served as my own starting-point.—I am, &c.,

Ed. Zetzsche.

TRADE NOTES AND NOTICES.

Tenders Invited.—The Ennis Town Commissioners invite specifications and tenders for the public and private lighting of the town of Ennis by electricity. Such specifications and proposals to be sent to Mr. E. Minikin, Town Clerk, Town Hall, Ennis, by January 1st. All expenses and costs incurred in the preparation of the said specifications and tenders to be borne by the parties sending in same.

Tenders Accepted.—The Liverpool Town Council have accepted the tender of the Liverpool Electric Supply Company (Limited) for laying electric mains to the Walker Art Gallery at £80.

Price List of Dynamos, &c.—Messrs. Charlesworth, Hall and Co., of Oldham, have issued a well-illustrated and fully descriptive list of their manufactures, together with numerous supplies sold by them. The dynamos are, as a rule, Gramme-wound. Numerous arrangements of dynamos are described, *e.g.*, one with a friction clutch, another with a turbine, and several combinations with engines. The projectors supplied by this firm are fully described, and directions for working them are given.

Digitized by Google

TENDERS RECEIVED.—At the meeting of the London County Council, on Tuesday, the following tenders were opened for installing the electric light at the central offices, Spring Gardens :—

J. D. F. Andrews and Co.	£1,490	0	0
Barclay and Sons	1,500	0	0
Fowler, Lancaster, and Co. (Limited)	1,564	0	0
J. Jackson	1,570	0	0
H. F. Joel and Co	1,586	0	0
J. R. Powditch and Co.	1,598	0	0
Harry South	1,604	0	0
Croggon and Company (Limited)	1,655	0	0
Drake and Gorham	1,731	0	0
F. G. Howard	1,745	0	0
Woodhouse and Rawson United (Limited)	1,810	0	0
Edmundson's (Limited)	1,815	0	0
London and Lancashire Electric Company	1,825	0	0
General Electric Power Company (Limited)	1,830	0	0
Paterson and Cooper	1,842	0	0
Reid Bros.	1,964	0	0
Electrical Supplies and Fittings Company	1,996	0	0
Mather and Platt	2,000	0	0
Planet Electrical Engineering Company (Limited)	2,056	8	2
Brush Electrical Engineering Company (Limited)	2,136	0	0
Crompton and Co. (Limited)	2,140	0	0
Latimer Clark, Muirhead and Co. (Limited)	2,192	7	0
W. Goolden and Co.	2,229	0	0
Ewart and Son	2,230	0	0
Johnson and Phillips	2,288	0	0
Sharp and Kent	2,300	0	0
Girdlestone and Co. (Limited)	2,300	0	0
Spagnoletti and Crookes	2,590	0	0
Lund Bros. and Co.	2,600	0	0
Siemens Bros. and Co. (Limited)	2,715	0	0
Laurence, Scott and Co. (Limited)	2,815	0	0
Suter and Co.	2,996	0	0

THE MANSION HOUSE.—The installation of the electric light in the Mansion House, which was undertaken by the Planet Electrical Engineering Company (Limited), was completed on Wednesday, when the building was visited by the General Purposes Committee of the Corporation, who expressed their satisfaction with the result.

MESSRS. DRAKE AND GORHAM.—This firm have in hand a complete electric lighting installation for Callarly Castle, which has been recently considerably altered and extended.

PRICE LIST OF CABLES.—Coincident with the reading of Mr. Preece's paper on the Specification of Insulated Conductors, the Telegraph Manufacturing Company, of Helsby, published a new list of cables. The list is arranged with great care, and contains much information. The "specification" of the insulations is given as in the following example :—"Tinned, 1 lap pure Para Rubber, 2 coats vulcanising I.R., 1 I.R. proofed tape. The whole vulcanised, 1 braid tarred, hemp or flax, well compounded." In addition to this, the over-all diameters of the cables are given, but the thickness cannot be directly ascertained. The diameters appear to be identically the same as those of the Silvertown make. Each class is described as offering so many megohms. This sheet is only one of half-a-dozen being issued by the Company, and the special Underground Mains and Concentric Cable Lists will, the Company inform us, contain many of the details suggested in Mr. Preece's Paper. The decrease of the resistance with the size of the conductor is already arranged for in the sheets now issued. It is to be hoped that all makers will revise their lists and re-issue them on one model, giving the information which is really wanted.

THE PHOSPHOR-BRONZE COMPANY.—This Company announce that they have acquired the sole licence for the manufacture of Bull's metals, which they now supply in ingots, billets, castings, forgings, stampings, rolled rods, and sheets. The great malleability, tensile strength, and durability of these alloys render them specially adapted for engineers, ship builders, and others requiring a strong non-corrosive metal of high quality and moderate cost. Mr. J. C. Bull, the inventor and patentee, has joined the Phosphor-Bronze Company as consulting engineer and chemist, and will superintend the manufacture of these alloys at the Company's various works.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

November 19, 1891.

20,141. C. EGGAR. Glasgow. A new or improved system of communicating visible signals and establishing electrical and telephonic connection between central town and district stations, and mechanism and appliances connected therewith.

November 20, 1891.

20,214. W. WHITE. London. Improvements in electropathic appliances.

20,217. J. S. FAIRFAX. London. Improvements in dynamo machines.

November 21, 1891.

20,226. T. B. GRANT. London. Improvements in arc electric lamps.

20,230. J. H. RIDER. Halifax. Improvements in electric arc lamps.

20,247. J. S. YULE and C. K. MARR. Glasgow. Improvements in solenoids, particularly applicable to automatic sound signalling apparatus, but which may also be used for other electrical purposes.

20,257. W. P. THOMPSON. Liverpool. An improved electric arc lamp. (La Compagnie de l'Industrie Electrique, successor and representative of La Société d'Appareillage Electrique, Switzerland.)

20,271. J. C. MORTON. London. A new or improved electric teething neck band for infants.

20,279. G. G. M. HARDINGHAM. London. Improvements in electric cables (The firm of Felter and Guilleaume, Germany).

SPECIFICATIONS PUBLISHED.

1890.

17,863. HARDT. Electric lamps. (Price 8d.)

18,554. PIERCE. Electrical conductors. (Price 8d.)

18,555. PIERCE. Electrical switches. (Price 6d.)

18,557. PIERCE. Electrical switches. (Price 6d.)

18,558. PIERCE. Electrical pendants, &c. (Price 8d.)

19,308. SWINBURNE. Electrical distribution of power by alternating currents. (Price 8d).

20,102. BAXENDALE. Dynamo-electric machines. (Price 6d.)

20,379. BAYLY (Loth). Electric conduit. (Price 8d).

20,896. GAY AND HAMMOND. Regulating electric currents. (Price 11d.)

1891.

40. HOOKHAM. Electricity meters. (Price 8d.)

200. BRIANNE. Electric arc lamps. (Price 8d.)

258. GAY AND HAMMOND. Electric arc lamps. (Price 6d.)

271. SCHOENERSTEDT. Electric arc lamps. (Price 8d.)

389. TEAGUE. Electricity meters. (Price 8d.)

587. BERLYN. Incandescent electric lamps. (Price 8d.)

COMPANIES' MEETINGS & REPORTS.

Oxford Electric Company (Limited).

On Saturday last the first ordinary meeting of this Company was held at the offices, 45, Broad-street, Oxford ; J. Irving Courtenay, Esq., Chairman of the Company, presiding.

The notice convening the meeting having been read,

The CHAIRMAN said : This is a formal meeting of the Company, called in compliance with the statute within four months from the incorporation of the Company, and is commonly known as the statutory meeting. There are no accounts to be presented, but the Directors gladly embrace the opportunity thus afforded of explaining the position of the Company, and inviting inquiry and cooperation from the shareholders and others attending the meeting. The Electric Installation and Maintenance Company obtained a Provisional Order, which was confirmed by Parliament on August 4, 1890, under which that Company has powers to supply electricity to the whole borough of Oxford. The Directors being desirous of establishing the business as a local enterprise, have made arrangements for transferring the Parliamentary powers to the Oxford Electric Company (Limited), and the necessary formalities are being carried out for obtaining the consent of the Board of Trade and the Corporation of Oxford to the grant of a Provisional Order for the purpose. In the meantime the Oxford Company having been duly constituted, entered into a contract with the Electric Construction Corporation of London and Wolverhampton, by which the Oxford Company purchases all the rights under the Provisional Order, and provides for the construction of a fully-equipped generating station for the supply of electricity, together with all necessary street works, mains, transformers, and storage batteries, for the supply of an important area which it is first proposed to deal with. This area comprises High-street, Cornmarket-street, Broad-street, Magdalen-street (from the corner of Beaumont-street to Cornmarket-street), and Catherine-street. The area in question, bounded by the streets named, comprises 12 colleges, 39 public buildings and churches, 9 hotels, and 337 shops, offices, and private houses. Provision is made in the contract for a supply of electricity sufficient for about 15,000 lamps actually connected with the Company's mains. The contract provides for the purchase of the lease of the land at Osney, formerly known as Cannon Wharf, the construction of the building, of which drawings may be seen on the walls, the generating and distributing plant, the cost of incorporating this Company and obtaining a transfer of the Provisional Order, a supply of lamps, wire, fittings, &c., to the value of £500, and a sum of £1,500 for the ordinary expenses of the Company. In the contract, the deposit of £1,500 as security paid to the Board of Trade is also provided for, but will be repaid to the contractors on satisfaction of the provisions of the order. Under this contract an agreement has been made for the erection of the generating station with Mr. Kingerlee, the well-known local builder and contractor, who is pushing on the work vigorously, and expects to have all completed by March. During the construction of the building the mains will be laid throughout the compulsory area, so that a supply of electricity will be furnished with all possible speed. The consideration for all these works and payments, including the Provisional Order, is a sum of £50,500, payable in fully paid-up shares of the Company. Assuming the capital expenditure to be

Digitized by Google

£50,000, the commercial result of the enterprise may be estimated as follows :—Revenue—258,750 units of electricity, at 8d., and rent of meters, £8,775 ; Expenditure—Running expenses, rent, salaries, insurance, &c., £5,200 ; net income (or 7 per cent. on £50,000), £3,575. The extension of the Company's business to the residential district north of the City and the other important parts of the Borough outside the area comprised in the above calculations, should materially add to the dividends of the Company, as the capital of £50,000 includes building, street works, &c., capable of providing for a larger business. The cost to the consumer at 8d. per Board of Trade unit is equal to about ¼d. per lamp per hour, or, in other words, the current necessary to supply 30 10-c.p. lamps for one hour or their equivalent for a proportionate time. Owing to the facilities for economising the use of electricity by the provision of a sufficient number of switches judiciously placed in the consumer's premises, it is found by experience that, though the relative cost of electricity at 8d. per unit, as compared with gas at 3s. per 1,000 cubic feet, appears to be higher, yet, in actual practice, the amount paid by the householder in each case would not materially differ; but when the convenience and advantages of the electric light, and its indirect economies, such as the saving in renewals of decorations and cleaning of rooms, are taken into account, it is really in the long run cheaper than gas. For a city like Oxford the electric light is almost a necessity. The experience already obtained at the South Kensington Museum and the British Museum proves the value of electricity as a means of illumination for such institutions, while the absolute safety of the method of supply adopted by this Company makes it specially suitable for lighting the various colleges, museums, and public buildings in the City with their priceless contents. I think a few words of explanation are necessary as to the system of electrical supply. I do not propose, however, to go into details, which have been already published, and Mr. Thomas Parker, the chief engineer of the Electric Construction Corporation, who has designed and is carrying out the installation, is here to-day, and will be ready to give any detailed explanation that may be required. The system proposed may be described as a moderate high-tension continuous current of 1,000 volts, with continuous-current transformers to convert to 100 volts, and secondary batteries to supply current to the lamps during the hours of minimum supply, thus allowing the generating station to be shut down entirely. The high-tension continuous current will be conveyed by underground mains, which never come in contact with the houses of the consumers, the electricity delivered to the consumers being absolutely safe, steady, and its continuity secured by the use of the storage batteries. Reliable meters will be supplied to each customer, and charged for by quarterly rental, as in the existing system of gas supply. The cost of fitting premises for the electric light varies with the character of the buildings and the nature of the fittings, which may be of a simple and inexpensive character, or costly designs according to the taste of the consumers. The Company have already been estimating for a few buildings in this City, which may be taken as typical, and comprise—Clarendon Press, 994 16 c.p. lamps, £1,326. 1s. 8d. ; Magdalen College, 675 16 c.p. lamps, £1,433. 18s. ; Christ Church, 595 16 c.p. lamps, £1,190 ; Metropolitan Bank, 45 16 c.p. lamps, £67. 10s. ; Young Men's Christian Association, 62 16 c.p. lamps, £86. 10s. The wiring and fitting of ordinary premises, such as dwelling-houses, shops, and hotels, with simple fittings, can be very well done at the cost of 30s per lamp ; factories and similar buildings at somewhat less ; colleges, museums and similar institutions according to the condition and character of the buildings. All work of this kind is done under stringent rules framed by the Fire Insurance Companies, and controlled also by the provisions for safety contained in the Provisional Order. No other method of artificial illumination can be compared with it for freedom from risk of fire, providing you have suitable fittings and a system of supply such as has been sketched out for the supply of the City of Oxford. As I have already stated, the Company has made its arrangements to carry out all the necessary works without any public issue of capital ; but the intention is, when the preliminary work is completed, to give the public an opportunity of subscribing to the capital, and thus the inhabitants of Oxford will be able to acquire an interest in this important local enterprise.

Mr. T. PARKER then explained matters of detail connected with the proposed system of supply, and incidentally mentioned that Sir William Thomson and Prof. Silvanus Thompson had both recently inspected the electrical plant prepared for this installation and that at Sydenham, and highly approved of the working of the continuous-current transformers, Sir William Thomson having expressed the opinion that their success would lead to the alternating-current system being eventually superseded.

A strong feeling in favour of the introduction of the electric light into the colleges, museums, &c., was very generally expressed, and the prospects of the Company appear to be highly satisfactory.

It was stated that the works were making rapid progress, and that the supply of electricity would be commenced early in the spring.

British Electro-Chemical Agency (Limited).

The first statutory general meeting of this Company was held on Thursday, December 10th, at Worcester House, Walbrook. Mr. Joseph Ebbsmith (the Chairman of the Company) presided.

The SECRETARY (Mr. W. J. Caulfield) having read the notice calling the meeting,

The CHAIRMAN said : Gentlemen, our duties this afternoon will be very brief indeed. As you are aware, this meeting is held in accordance with the provisions of the articles of association—that a general meeting should be called within four months of the registration of the Company, a period which has well-nigh arrived. We do not lay before you any detailed report at this meeting, but it will perhaps be satisfactory for you to learn that the operations of the Company, so far, have more than justified the expectations of the Directors at the time the Company was formed, and when the present shareholders were invited to subscribe. Possibly the results may be of a nature which will be very gratifying indeed to the shareholders, when the general report and balance-sheet are issued. It is proposed to make up our accounts for the financial year to June 30, 1892, but I am at liberty to disclose to you that the affairs of the Company are in such a state that the Directors confidently anticipate their ability to declare a satisfactory interim dividend at the expiration of the six months' working. In reply to inquiries which had been made as to the prospect of calls, I can only say that the power of making calls will be exercised if and whenever the Directors are satisfied that the interests of the Company will be advanced by further share capital, but at the present time there is no prospect of our making any call whatever. We have been fortunate enough already to deal with some of the interests of the Company—what I may, perhaps, term the minor interests of the Company—and we are at the present time in the extremely sound and satisfactory financial position of having our capital intact, and also of having such an increment of profit as appears to be quite sufficient for the immediate requirements of the Company. I shall be very happy to answer any questions which may be asked, but I think I may take it that the remarkably limited attendance of shareholders at the meeting to-day is an evidence that they are satisfied their interests will be safeguarded by the Directors. And although this is essentially a speculative Company, they may be quite sure that the Directors do not intend to incur any unreasonable risks which might prejudice the profits they have already made, and which they have the continued prospect of making.

There being no motion, the meeting closed with a vote of thanks to the Chairman.

The Gulcher (New) Electric Light and Power Company (Limited).

The following report has been issued by the Directors of this Company. The fourth ordinary general meeting will be held at Winchester House, E.C., to-day (Friday), at 12 o'clock :—

The meeting has been called to comply with the Statute, and the Directors intend to move a resolution adjourning the meeting for two months, by which time the Chairman, who is now on his way, will have returned from New Zealand, and will be able to furnish a full report of the results of his visit. The Directors do not propose to submit the usual balance-sheet to the shareholders until the date last mentioned, as the Auditor informs them that it is impossible for him to deal with certain accounts affecting the New Zealand business until these accounts are furnished by the Chairman in a more complete form.

The Directors notify that the Chairman's visit to New Zealand has been entirely successful. During the time he has been out there he has succeeded in obtaining Acts of Parliament for the private lighting of Wellington, Christchurch, and Auckland, and these have passed through both the Upper and Lower Houses of Parliament. He has also concluded a fresh contract with the Corporation of the City of Wellington for the public lighting of that city in lieu of the existing one, and in addition to the contract for the privale lighting, both of which contracts are of a satisfactory character.

Fowler-Waring Cables Company (Limited).

The following is the report of the Directors, to be presented to the shareholders at the third ordinary general meeting, to be held at Winchester House (Hall No. 47), Old Broad-street, London, E.C., to-day (Friday), at 1 p.m. :—

In submitting their second annual report, the Directors express their regret that they are unable to show a profit on the work of the year. At the same time they are glad to say that the business of the Company has made great progress. There has been a marked increase in the volume of business done as compared with last year, and the gross profit has been sufficient to cover all ordinary, and some extraordinary, expenses.

The factory is now well equipped and organised, and the work done there is unsurpassed. Since the close of the financial year numerous orders have been received, to say nothing of many important inquiries. The Directors, therefore, fully retain their previously-expressed confidence in the business, further details of which will be found in the annexed report of the General Manager. There is, however, no manufacturing business in which the competition is keener than it is in ours, and a new undertaking must necessarily require time for development and to make its manufactures known. Meanwhile, as materials must be paid for almost on delivery, and as it is often necessary to give considerable credit to our customers, as well as to provide for special additions to plant to enable us to meet the new demands constantly being made by electrical engineers, the Directors believe that the employment of a larger working capital than the Company possesses would be justified by results and would materially assist in bringing the concern to a dividend paying position. The Directors have again not drawn their fees, but on this occasion they have debited the amount in suspense, as they anticipate a state of things when the payment of this amount will be fully justified by the condition of the business.

The retiring Directors, Mr. Walter Chamberlain and Mr. R. W. Eddison, being eligible, offer themselves for relection. The auditors, Messrs. Cooper Brothers and Co., offer themselves for re-election.

General Manager's Report.

During the past year the Company has made notable progress in each department of its work, and our manufactures have been successfully applied and their efficiency proved in every important branch of electrical engineering. In electric lighting, among the larger orders we have delivered to the London Electric Supply Corporation ten miles of large

Digitized by Google

concentric conductors for the distribution of their high-tension currents through the streets of London. These cables are now laid, and are working daily under conditions which demand the most perfect efficiency; the best testimony to their success is the fact that the Corporation have ordered an additional ten miles to be delivered during the next few months. In ship lighting, eight of the new warships at present building for the Admiralty have been wired by cables of our manufacture, and some of the large shipbuilders have adopted them for installation on board the steamships building in their yards. In the electric lighting and transmission of power in mines, the cables have been extensively used, and they contribute very greatly to the success of this difficult and important work. We have also manufactured special wire for use with the explosives employed in blasting and torpedo experiments, and for many more of the ever-increasing number of electrical applications.

In telegraphy, the leading railway companies are adopting lead-covered wires for the tunnels, yards, and stations, and many miles of our cables have been so used during the past year.

In telephony, the Government has employed our cables exclusively for the London end of the Paris telephone lines, and also for connecting up the various centres in London. Large orders have also been entrusted to us by the private telephone companies, and we are at present laying a 100-wire cable through Paris for the French Government telephone service. We have recently despatched fifteen miles of similar cable to Sydney for the Government telephone service there. Only our cables will be employed for the new Central Station at Sydenham, which will supply electric light to the Crystal Palace during the forthcoming Exhibition. Other large orders are in hand, and the prospect of future business is exceedingly good. In my last report I referred to the fact that rubber-covered wires were often specified to the exclusion of all others, and that we deemed it advisable to be prepared to supply these if it became necessary. In many instances we have been able to secure the adoption of our cables in preference to those which are rubber covered, and all the work referred to in this report has been carried out with cables manufactured under those patents and processes which are the exclusive property of the Company.

The works at North Woolwich have never yet been worked to anything approaching their possible output, and consequently we cannot yet show a profit on our work. Sufficient, however, has been done during this year to demonstrate not only the value of our manufactures and the extent and variety of their application, but to justify the firmest confidence in the future of the Company.

The Electric Construction Corporation (Limited)

The following is the report of the Directors of this Corporation to be submitted to the shareholders at the ordinary general meeting, to be held at Cannon-street Hotel, E.C., on Tuesday next, the 22nd inst., at three o'clock:—

In submitting the accounts of the Corporation up to 30th September last, the Directors point out that the period embraced by the previous profit and loss account extended over nearly 16 months, whereas the present report only includes the working at Wolverhampton for one year, and at the Millwall Works for eight months. The Directors are happy to state that the business of the year has been of a satisfactary and promising character, and it will be seen from the accompanying accounts that it has resulted in a profit balance of £46,166. 16s. 8d., from which the Directors have carried £10,000 to reserve for depreciation, leaving a net balance of profit and loss for the year of £36,166. 16s. 8d., which, with the £3,877 11s. 1d. carried forward from last year, makes a total of £40,044. 7s. 9d. available for disposal.

The development of the electro-chemical patents of the Corporation is advancing to the satisfaction of the Directors, and a substantial addition to future profits may be expected from this source. As the shareholders are already aware, Mr. Ebbsmith has resigned his appointment as Managing Director of this Corporation in order to take charge of the British Electro-Chemical Agency (Limited), to which these patents have been transferred: but in order that the Corporation might not be deprived of the benefit of his experience, he has been elected to fill the vacancy on the Board, caused by the lamented death of Sir Robert Fowler.

The Directors have leased the Millwall Works on favourable terms to the Electrical Power Storage Company (Limited), with an exclusive licence to that Company to use the Storage Battery Patents belonging to the Corporation. This arrangement has already proved of great advantage to both parties, and it has the further merit of enabling the manager and chief engineer, Mr. Parker, to concentrate his energies on the important contracts and work which the Wolverhampton Works have in hand.

In continuance of their previous policy, as approved by the shareholders at the last general meeting, the Directors have written off capital expenditure the sum of £20,000 out of the sale of the patents sold or transferred to other Companies during the past year. The sale of these patents will not in any way prejudice the working of the Corporation; on the contrary, it is confidently expected that their development will bring a considerable amount of work to the factory at Wolverhampton.

The Directors have pleasure in recommending a dividend of 6 per cent., payable on January 22nd next, leaving a balance of £10,721. 19s. 4d. to be carried forward to the present year's account. The prospects of business are very satisfactory. The Corporation is at present carrying out, in addition to ordinary work, large and important contracts for the Liverpool Overhead Railway, the Electric Lighting of the City of Oxford, and also for the electrical plant for the Crystal Palace district.

The balance of the authorised debenture issue is now required for the working of the Corporation, and the Directors will be glad to receive applications, as soon as possible, on the form issued with the report, in order to avoid the expense of a public issue.

In conclusion the Directors desire to express their continued and increased confidence in the future of the undertaking.

In accordance with the Articles of Association four of the Directors, viz., Sir Henry Mance, with Messrs. Ebbsmith, Holt, and Moseley, retire from the Board, all of whom are eligible, and offer themselves for re-election. Messrs. Broads, Paterson, and Co., the present auditors of the Corporation, retire, and offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

CALIFORNIA GAS, WATER, AND ELECTRIC LIGHT COMPANY SYNDICATE (LIMITED).—This Company was registered on December 10, 1891, with a capital of £2,000, in £1 shares, by Oldfield, Barham, and Oldfield, St. Stephen's Chambers, Telegraph-street, E.C. The objects are to adopt and carry out agreements for the acquisition of any concessions, rights, or interests relating to gas, water, or electric works, businesses, or concerns in the United States of America, in Canada, and in the Colonies of Great Britain, and to lease or otherwise acquire and carry on such works. The regulations contained in Table A of the First Schedule of the Companies' Acts, 1862, mainly apply. Registered office: 20, Bucklersbury, E.C.

CHLORIDE ELECTRICAL STORAGE SYNDICATE (LIMITED).—This Company was registered on December 12, 1891, with a capital of £262,500, divided into 250,000 Ten per Cent. Preference and 12,500 Founders' shares of £1 each, by the Solicitors to the Company, Hay, Schmettau, and Co., 31, Abchurch-lane, London, E.C. The objects are to adopt a provisional agreement dated November 30, 1891, made between the Electric Storage Battery Company and the United Gas Improvement Company of the one part, and J. A. E. Hickson (for this Company) of the other part, for the sale to the Company of certain patents and other property; to carry on the business of working such patents, and to construct, contract for, establish, carry on, or to finance or provide capital for companies, firms, persons, &c., to enable them to construct, establish, and carry on any works and machinery or apparatus for lighting streets or other places, public and private, by electricity, and for the production, transmission, storage, and use, by any means and for any purpose, of light, heat, electric, magnetic, or other force; to carry on the business of ironmasters, copper smelters, steel makers, iron founders, engineers, boiler-makers, metallurgists, &c.; to carry on the business of an electric light company in all or any of its branches; to construct, lay down, establish, fix, and carry out all necessary cables, wires, accumulators, lamps, and works; and to carry on the business of electricians, electrical engineers, electrical contractors, and suppliers of electricity. The number of Directors shall not be less than three nor more than nine, two of whom shall form a quorum. The first Directors shall be elected by the subscribers, subject to the right reserved to the vendor to nominate one-third of the Board, and until such election, the subscribers shall act as Directors. Qualification: 500 Preference shares. Remuneration: £1,500 per annum divided between them as they themselves determine.

LONDON WARMING AND VENTILATING COMPANY (LIMITED).—Registered by S. F. Taylor, 5, Gray's Inn-square, W.C., with a capital of £10,000, in £1 shares. Object: The acquisition of the undertaking of the London Warming and Ventilating Company, and generally to carry on business as manufacturers of, and dealers in, all kinds of heating, lighting, and ventilating apparatus, electric and otherwise. There shall not be less than three nor more than seven Directors, the first being appointed by the signatories to the Memorandum of Association. Qualification: £50. Remuneration to be determined by the Company in general meeting.

MOUNTAIN'S WIRE MANUFACTURING COMPANY (LIMITED).—This Company was registered on December 10, 1891, with a capital of £25,000, in £5 shares, by Edmonds and Edmonds, 9, Gray's Inn West, W.C. The objects are to take over and carry on the business of nail and brass wire manufacturer, carried on by B. Mountain, at Castleford, Yorkshire; to acquire the whole of the right and title in a British patent, No. 11,429 of 1890, for an invention for improvements in the manufacture of brass and other soft metallic wires; and also the letters patent taken out in France, No. 208,849 of 1890; Belgium, No. 92,303 of 1890; Germany, No. 57,672 of 1890; and the United States of America, No. 372,716 of 1890. The first Directors are W. H. C. Dunhill, W. Fawcett, H. Goodall, J. Horne, and B. Mountain (Managing Director).

NORTHUMBRIAN CHEMICAL COMPANY (LIMITED).—This Company was registered on December 12, 1891, with a capital of £60,000, in £10 shares, by Pattison, Wigg, and Co., 11, Queen Victoria-street, E.C. The objects are to carry on business as manufacturers of chemical products and drugs, of sanitary and disinfectant preparations, manure, soap, &c., and as general merchants and mechanical, chemical, and electrical engineers. The first Directors are J. D. Milburn, W. G. Woods, T. G. Dunford, and J. C. Rollin, all of Newcastle.

COUNTY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The statutory return of this Company, made up to November 30, 1891, was filed on December 7, 1891. The Company was registered on June 30th last, with a capital of £100,000, in £5 shares, to carry on the business of an electric light, heat and power supply company in all or any of its branches. At the date of making up, 200 shares had been taken up, and £1 called upon each. £190 is paid in respect of calls, leaving £10 unpaid. The annual general meeting was held on November 16, 1891. No agreements for the taking over of any business, contracts, or concessions, have been filed. The principal shareholders are the Brush Electrical Engineering Company (Limited), 35 shares, and the Electric and General Investment Company (Limited), 100 shares. Registered office: 1, Great Winchester-street, London, E.C.

Digitized by Google

ELECTRICAL ASSETS PURCHASE COMPANY (LIMITED).—The statutory return of this Company, made up to November 23, 1891, was filed on the same day. The Company was registered on July 28, 1891, with a capital of £1,000, in £1 shares, to take over the business and assets of the Liepmann Carbon Company (Limited). 564 shares have been taken up, 500 of which have been issued as fully paid to the Liepmann Carbon Company (Limited), in pursuance of an agreement made November 5, 1891 (filed on the 12th following). Upon the remaining 64 the full amount has been called and paid. Registered office: Eastcheap Buildings, 19, Eastcheap, E.C.

ELECTRICAL FINANCE CORPORATION (LIMITED).—Memorandum of agreement made December 8, 1891 (filed on the 11th), between William Martin, of No. 12, Poplar-grove, Shepherd's Bush, in the County of Middlesex, gentleman, of the one part, and Charles Edmund Baker, of No. 22, Great George-street, in the City of Westminster, as trustee for and on behalf of a Company registered in the name of the Electrical Finance Corporation (Limited), of the other part, whereby it is agreed as follows:—(1) The said William Martin shall provide by himself or his friends the money necessary for registering the above-named Company, and pay the expense of preparing and printing the Memorandum and Articles of Association of the Company and the preparation of the prospectus. (2) In consideration therefore the said C. E. Baker doth, at the request of the said W. Martin, hereby agree, on behalf of the Company, that the first 50 Founders' shares, numbered 1 to 50 inclusive, shall be allotted as fully paid to the said William Martin or his nominees. This Company was registered on November 18th last, with a nominal capital of £100,000, divided into 19,800 ordinary and 200 Founders' shares of £5 each.

ELECTRIC LIGHTING COMPANY (LIMITED).—The following notices were filed on December 8, 1891:—"In the matter of the Companies Acts, 1862 to 1890, and in the matter of the Electric Lighting Company (Limited). To the Registrar of Joint Stock Companies, Somerset House, W.C. Dear Sir,—I beg to inform you that a general meeting of the above-named Company was held at my offices, No. 1, Queen Victoria-street, in the City of London, on Thursday, November 26th last, in accordance with Section 142 of the Companies Act, 1862, at which meeting an account was submitted, showing the manner in which the winding-up has been conducted, and the property of the Company disposed of. Minutes of the proceedings at such meeting are sent forthwith. Your obedient servant, ROBERT A. MCLEAN, liquidator." The liquidator reported that the Company was formed, as the shareholders were aware, in the early days of electric lighting, for the purpose of working what was then known as Wilde's process. The entire capital of the Company was supplied by the signatories to the Memorandum and Articles of Association, and their operations were in the nature of an experiment to ascertain, at their own cost and risk, whether the process was likely to be commercially successful before inviting the public to subscribe. The greater part of the capital was paid to Mr. Wilde for the use of his process, and the rest was expended in numerous experiments and trials at the South Kensington Museum, the Polytechnic, the Gaiety Theatre, and elsewhere, the result being, after eight months of labour, that the Company came to the conclusion that the process was not likely to be a success, and resolved to liquidate. The above-named Company was registered on October 5, 1878, with a capital of £100,000, in £10 shares. The signatories were:—Baron Emile Erlanger, of 43, Lothbury, 225 shares; R. J. Hood, 10; Sir Philip Rose, 10; J. Hollingshead, 10; Lionel Lawson, 225; C. F. de K. Steuart, 10; and R. A. McLean, 10, making a total of 500 £10 shares taken up. No further returns have been filed.

"ENERGY" GAS, ELECTRIC LIGHTING AND POWER COMPANY (LIMITED).—The statutory return of the above-named Company, made up to December 10, 1891, was filed on the same day. The Company was registered on August 1, 1891, with a nominal capital of £20,000, in £1 shares. Seven shares only have been taken up, upon which nothing has been called, the original subscribers being the only shareholders. Registered office: 5, Chancery-lane, London, W.C.

EPSTEIN ELECTRIC ACCUMULATOR COMPANY (LIMITED).—The statutory return of this Company, made up to December 1, 1891, was filed on the 10th following. The Company was registered on July 31, 1891, with a capital of £101,000, divided into 100,000 ordinary and 1,000 founders' shares of £1 each, to acquire the patents and patent rights of Mr. Ludwig Epstein, relating to the invention of improvements in the manufacture and use of secondary or storage batteries, and to work the same. An agreement made July 31, 1891, between Woodhouse and Rawson United (Limited), of the first part, L. Epstein of the second part, and this Company of the third part, stated that it was agreed that L. Epstein should be Managing Director, with a remuneration of £100 per annum, and 10 per cent. of all net profits, except those made from the sale of patents or the sale or granting of licences. It was also agreed that in respect of the purchase of the patents £31,500 in fully paid ordinary shares, and £450 in fully paid founders' shares should be paid to L. Epstein, and that £38,700 in fully paid ordinary and £550 in fully paid founders' shares should be paid to Woodhouse and Rawson United (Limited). The patents sold to the Company are:—England, Nos. 3,770 of 1882, 9,195 of 1884, 4,527 of 1887, and 350 of 1890; France, Nos. 162,730 of 1884, 182,219 of 1887, and 205,218 of 1890; Belgium, Nos. 65,464 of 1884, 76,744 of 1887, 78,705 of 1887, and 90,289 of 1890; United States of America, Nos. 382,420 and 383,216 of 1888, and 425,999 of 1890; Italy, Nos. 17,060 and 77 of 1884, 21,406 and 362 of 1887, and 27,352 and 420 of 1890; Cape of Good Hope, No. 664 of 1891; South Australia, No. 1,854 of 1891; India, No. 47 of 1891; New South Wales, No. 2,802 of 1891; and Victoria, No. 8,494 of 1891. Patents applied for in Canada, Sweden, Queensland, New Zealand, and Spain are included. At the date of the making up all the founders' and 70,207 of the ordinary shares were taken up, and upon 200 ordinary 5s. per share had been called and paid. The remaining 1,000 founders' and 70,007 ordinary shares were issued as fully paid. The working capital of this Company appears by the above statement to be very small, but this is supplemented by a loan of £7,500, bearing interest at 5 per cent. per annum from Woodhouse and Rawson United (Limited). Registered office: 34, Cannon-street, London, E.C.

INTERNATIONAL ELECTRIC SUBWAY COMPANY (LIMITED).—An agreement dated December 3, 1891 (and filed December 12th), between W. H. Johnstone, of Philadelphia, U.S.A., electrical engineer, and F. W. Toppan (called the vendors) of the one part, and the above-named Company of the other part, states that, whereas by an agreement dated November 23, 1891 between the same parties, it was agreed that the vendors should sell and the Company should buy certain letters patent, and that as part of the consideration for the said sale the Company should issue to the vendors or their nominees 5,000 £1 shares, fully paid, it is hereby agreed that on the completion of the said sale the Company shall issue the said shares, numbered 8 to 5,007 inclusive, to the vendors or their nominees, in full satisfaction of that portion of the purchase money which was to be satisfied by the allotment of fully paid shares. Another agreement of the same date and between the same parties states that, whereas it was agreed that certain patents and other property should be sold to the Company, it was now agreed that the vendors should accept the allotment of 15,000 fully paid £1 shares in the purchasing Company in full satisfaction of that portion of the purchase money, which was to be satisfied by the allotment of paid-up shares. Offices: 43, Threadneedle street, London, E.C.

ITALIAN ELECTRICAL LIGHT AND POWER COMPANY (LIMITED).—The statutory return of this company, made up to November 30, 1891, was filed on December 7th following. The nominal capital is £60,000, in £4 shares. The Company was registered on July 17th last, to carry on the business of an electric light, heat, and power supply company in all or any of its branches, and particularly to enter into an agreement, dated July 18, 1891 (filed on the same day), between the Cavalieri Girolomo Taddei, of 83, Via Avenula, Rome, civil engineer, and this Company, for the sale to the Company of three electrical installations in Italy, and which states that, in full consideration for such installations, Girolomo Taddei agrees to accept 1,743 fully-paid £4 shares, numbered 8 to 1,750 inclusive, to be allotted either to him or his nominees. At the date of the making-up 307 shares were taken up, 300 of which had been issued to Girolomo Taddei as fully paid. Upon the remaining 7 nothing has been called. The original subscribers are at present the only shareholders. Registered office: 10, Austin-friars, London, E.C.

VENEZUELA TELEPHONE AND ELECTRICAL APPLIANCES COMPANY (LIMITED).—The annual return of this Company, made up to December 4, 1891, was filed on December 11th following. The Company was registered on April 22, 1890, with a nominal capital of £70,000, in £1 shares. All the shares have been taken up, and upon 13,494 the full amount has been called and paid. The remaining 56,506 were issued as fully paid. The principal shareholders are Messrs. Westendorp and Co., bankers, of Amsterdam (1,500 shares); Paul Bevez, of 21, Avenue Montaigne, Paris (3,000); Sir Douglas Fox, of Coombe Springs, Kingston-on-Thames (2,500); Messrs. G. Blancke, Zoon, and Co., bankers, of Amsterdam (56,056); and J. Balli, of 20, Great Winchester-street, E.C. (4,000). Registered office: 37, Lombard-street, London, E.C.

WOLVERHAMPTON ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return of the above-named Company, made up to February 18, 1891, was filed on December 10, 1891. The Company was registered on June 18, 1889, with a capital of £50,000, in £10 shares. 23 shares only have been taken up, the full amount has been called upon each, and all calls paid. No agreements for the taking over of any businesses, concessions, contracts, or plant have been filed, and all shares are taken up locally. Registered office: Wolverhampton.

CITY NOTES, &c.

BRIGHTON AND HOVE ELECTRIC LIGHT COMPANY (LIMITED).—The prospectus of this Company will be found in our advertising columns. The Company is registered with a capital of £100,000, in 20,000 shares of £5 each, of which £15,000 has already been issued and is fully paid up. The present issue is for £15,000 First Mortgage Debentures in 150 Six per Cent. Debentures of £100 each, repayable at par on January 1, 1895, or earlier, at the Company's option, at £105, interest payable half-yearly in January and July of each year. £12,500 is the balance remaining for issue, and the Company is prepared to receive application for the amount at par. Payable, £10 on application, £15 on allotment, £25 on February 1st, £25 on March 1st, and £25 on April 1, 1892. The capital asked for in the present issue is required, the prospectus states, to enable the Company to deal with the large increase of business which is springing up. The Company owns the Central Station at Brighton, which has been supplying that town with electricity since 1882, which was only taken over by the Brighton and Hove Company in November, 1885, and the following dividends have been declared since that time:—1886, 4 per cent.; 1887, 1888, 1890, 5 per cent. each year. The Company's lighting area is about 14 miles in extent, and the mains tap the most eligible portion of Brighton and Hove. The bankers of the Company are the London and County Bank (Limited), Brighton, and the lists of applications will close to-morrow (Saturday), the 19th inst.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts of this Company for the week ended December 16th amounted to £815; aggregate receipts for half-year to date, £17,568.

CROMPTON AND CO. (LIMITED).—The Directors of this Company have declared an interim dividend at the rate of 7 per cent. per annum on

Digitized by Google

the preference shares, and 5 per cent. per annum on the ordinary shares, for the half-year ended 30th September last.

EASTERN EXTENSION TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend for the quarter ended September 30 last of 2s. 6d. per share, free of income-tax, payable on January 15 next.—This company notify that the coupon on the Five per Cent. Australian Government Subsidy Debentures, due on January 1st next, will be payable on and after that date at Messrs. Barclay, Bevan, and Co.'s, 54, Lombard-street, E.C. Coupons must be left three clear days for examination.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY.—This Company notify that the coupons due on January 1, 1892, on their Five per Cent. Mortgage Debentures will be paid on and after that date at the banking house of Messrs. Barclay, Bevan, and Co., 54, Lombard-street, E.C. Coupons should be left at the bank three clear days for examination.

ELECTRIC CONSTRUCTION CORPORATION (LIMITED).—This Corporation invite applications for the balance of their Six per Cent. First Mortgage Debentures of £100 each. Forms of application may be obtained of the bankers of the Corporation, Messrs. Prescott, Dimsdale, Cave, Tugwell, and Co. (Limited); or at the office, Worcester House, Walbrook, E.C.

EUROPEAN SIMS-EDISON ELECTRICAL TORPEDO COMPANY (LIMITED).—Major-General E. Harding Steward has joined the Board.

ST. JAMES AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED). It is announced that the 10,000 new £5 preference shares recently offered to the shareholders of this Company were allotted on the 11th inst. at £1 10s. premium.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The coupons due December 31st on the debentures of the West Coast of America Telegraph Company (Limited) will be paid by Messrs. Barclay and Co., Lombard-street. The coupons must be left three clear days for examination.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 710.—Vol. XXVIII. FRIDAY, DECEMBER 25, 1891. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6.

NOTES.

The preliminary steps which have been and are being taken in connection with the proposed International Electrical Congress to be held at Chicago in 1893 have given rise to a somewhat heated dispute. In Chicago some talk of "unparalleled audacity," coupled with "effrontery," and "impudent and snobbish editorials," and New York retorts with allegations of "high-handed indifference." "The very head and front of offending" has been the appointment of Prof. Gray and a posse of Chicago electrical celebrities (to the complete exclusion of the members of the American Institute of Electrical Engineers) to set the Congressional machinery in motion. The Federal Government is much to be pitied. In its endeavours to please everyone it satisfies nobody, and with the ever latent jealousy between New York and Chicago fully aroused every appointment is a signal for a recriminatory chorus. The Exhibition is, however, eighteen months distant, and we make no doubt that by May, 1893, the present storm in a tea-cup will have subsided, and a satisfactory compromise have been effected.

The proposed International Electrical Congress is perhaps the most promising international feature of the whole Exhibition. By the summer of '93 there will be several matters connected with nomenclature, units and definition awaiting imprimatur; and what soil more appropriate than that of America on which to formally admit the names of Franklin and Henry into the electrical Temple of Fame. The Chicago Exhibition will have been justified, if it be the occasion of the holding of a truly representative International Electrical Congress, which confines itself to its proper work and avoids farcical discussions in half-a-dozen tongues on subjects outside its jurisdiction.

At the meeting of the Physical Society on Friday last, an interesting discussion arose as to the exact meaning properly or generally conveyed by the word *inductance*. One of a numerous and useful class of words suggested by Mr. Heaviside in his articles on electro-magnetism published in *The Electrician*, some years ago, this expression has proved so handy and appropriate that it has come into common use, but apparently it is employed in two senses. Some use it as a shorter and more convenient term for L, the coefficient of self-induction, while others employ it to represent the value of $2\pi n$ L, where n is the frequency of the current in periods per second. In the theoretical investigation of alternate currents it rarely happens that the coefficient L appears in the formulæ except in company with the multiplier $2\pi n$; so that it would appear more convenient to use the word *inductance* to represent the whole expression $2\pi n$ L rather than L alone. On the other hand, the expression *coefficient of self-induction* is so cumbrous as to render a briefer term desirable, and the convenience of the word *inductance* is sometimes shown by its use in both senses by the same writer. Mr. Heaviside originally introduced the word to represent L alone, but it has perhaps been more generally used to denote $2\pi n$ L than L, and an advantage of this arrangement is the simple relation which then obtains between resistance, inductance, and impedance. These three important quantities are then each measured in ohms, and their magnitudes are always represented by the sides of a right-angled triangle, impedance being denoted by the length of the hypotenuse. The word inductance is one which has come to stay, and it is therefore desirable to fix its meaning as soon as possible and to choose that meaning which will render it most useful.

The induction coil has at various times formed the subject of much important work. The early researches of Blaserna, Bernstein, and Helmholtz were carried out when electricians were much less familiar than they are at present with the character of electric oscillations; yet these investigations clearly showed the wavy nature of the currents in the coils at the moment of making or breaking the primary circuit, and our readers will find an excellent description of them from the pen of Dr. Fleming, in *The Electrician* for December 28, 1888, and for January 4, 1889. After the great work of Hertz had focussed the attention of scientific men on the subject of electro-magnetic waves, it occurred to Dr. Fleming that the action of the condenser in an induction coil was such as to form essentially a resonance phenomenon. His views were explained in an article printed in our issue for May 31, 1889, and were afterwards criticised in our columns by Mr. C. V. Boys and Dr. Lodge. Any one interested in the theory of the induction coil cannot do better than refer to these articles, as the subject is treated from three distinct points of view, while the conclusions arrived at are very similar. In the present issue also we print an interesting article by M. Colley, which will be found worthy of study in connection with those just referred to. The subject is treated chiefly

Digitized by Google

from the experimental side, and the investigation brings out prominently the effect on the character of the discharge, produced by variations in the capacity of the condenser employed, and in the self-induction of the primary and secondary circuits.

Central London Railway.—The preliminary borings for the Central London Railway reveal satisfactory conditions.

Huddersfield.—At a meeting of the Huddersfield County Council on Wednesday, Mr. W. C. Mountain, of Newcastle-on-Tyne, was appointed electrical engineer, at a salary of £200.

The Specification of Insulated Conductors.—On page 161 of our last issue, for $\sigma = R' l \times \frac{d+t}{t}$ read $\sigma = R' l \pi \times \frac{d+t}{t}$.

Rathite.—Rathite is a new insulating compound, composed of vulcanised india-rubber and silk fibre. The idea is to apply this form of insulation in all cases where solidity rather than flexibility is wanted. The compound is due to MM. Waddington, Rath et Cie.

The City and Guilds of London Institute.—On the motion of Mr. Shaw, seconded by Mr. A. A. Wood, it was resolved at the last meeting of the Common Council to instruct the Coal and Corn and Finance Committee to consider the present position of the above Institute, and to report their opinion thereon.

Inter-urban Telephony in Spain.—No tender having been presented to establish the direct telephone lines between Madrid and the important provincial towns of Cordova, Seville, and Cadiz, the Spanish Government, says *Industries*, has decided to establish those lines as a national service, and the erection will be proceeded with at once.

The Ardois System of Electric Night Signals.—The U. S. cruiser "New York," which was launched on the 2nd inst., is to have a most elaborate electric plant. The Ardois system of electric night signals is to be used. This system was briefly described in *The Electrician* some little time ago, and consists of yard-arm lanterns permitting 62 combinations from a key-board.

Puebla.—The town of Puebla (Mexico) has now to be added to the already long list of towns which are actually obtaining, or seriously proposing to obtain, electric energy from a distant source. The generating plant comprises three 50-H.P. 2,200-volt alternators, driven by turbines. The motive power is a 33ft. waterfall, capable of giving 600 H.P., and situated six miles from the centre of the town.

Terrestrial Magnetism.—Terrestrial magnetism and solar physics, in their relation to meteorology, is to be made the work of a special department in the Weather Bureau. Prof. Frank H. Bigelow, late assistant in the *Nautical Almanack* office, will be in charge. Prof. Bigelow's recent discoveries regarding the solar corona and terrestrial magnetism, says *Engineering News*, especially fit him for this post.

Dielectric Constants.—In a Paper read at a recent meeting of the Académie des Sciences, M. Lefebvre stated that he had determined the following dielectric constants:—Sulphur, flower and roll, 2·6; sulphur, cast in rolls six months previously, 3·9; ice, different specimens, 3·45 and 2·4; ebonite, 2·3; paraffin, brown, 2·1; white ditto, 2·0; petroleum, 1·9; carbon bisulphide, 1·7; spirits of turpentine, 1·5.

A New American Engineering Firm.—The *Electrical World* announces that Mr. Frank J. Sprague, Dr. Louis Duncan and Dr. Cary T. Hutchinson have combined their energies, and will enter the field of general electrical engineering under the firm name of Sprague, Duncan and Hutchinson, with offices at 15, Wall-street. The new firm propose to do a consulting and supervising business without personally undertaking contracts.

Electric Mining Lecture.—There was a large attendance of members of the Midland Counties branches of the National Association of Colliery Managers in the large Lecture Theatre of Nottingham University College, on Saturday last, to hear Prof. Robinson deliver one of the series of lectures arranged for by the Association and the Technical Education Committees of the Notts and Derbyshire County Councils. Prof. Robinson took for his subject "Electricity as Applied to Mining."

Calcutta.—The Calcutta Municipal Commissioners have decided to light the New Central Road by electricity. The Howrah Bridge has now been lighted by electricity for several months with complete success. The road, which is now completed, except one short section, will be nearly two miles long. It is expected, says the *Indian Engineer*, that the lights will be ready to work soon after the last section of the road is finished, which will be in the course of this cold weather.

Primary Battery Competition.—Our Milan contemporary, *L'Elettricita*, announces an international competition for a prize of £80, to be awarded to the inventor of a new, practical, simple, and commercial battery. The competition will remain open from January 1, 1892, until August 31st of the same year. The jury, we are told, will be composed of competent and estimable individuals. Further particulars may be obtained from the editor of *L'Elettricita*, 2, Via Meravigli, Milan.

Glow-Lamp Stealing.—For some time past the incandescent lamps at the Paris Theatres have been the object of the polite attentions of a thief, who has just been arrested by a clever device of the management of the Porte St. Martin. As it was found that a great many lamps had disappeared at that house, the electrical engineer so arranged matters that immediately a lamp was removed an alarm was sounded. The man was thus caught as he was making away with the lamp in his pocket. It is believed that he has a large store of stolen lamps.

Electric Lighting in Chelsea.—During 1890 some 100 houses adopted electric lighting in Chelsea. At the end of February last the number of houses lighted by the several companies was:—

	1889-90.	1890-91.
Chelsea Electricity Supply Company ...	113	215
Cadogan Electric Light Company	25	16
London Electric Supply Corporation ...	1	2
	139	233

The Artesian Well in the City.—At a recent meeting of the Commissioners of Sewers, the Engineer reported upon the artesian well which the Commissioners are sinking at the artisans' dwellings in the Minories. He stated that the well had been bored to an additional depth of 100ft., making 450ft. in all; the average daily yield being 50,000 gallons. He recommended that the boring should be continued for another 100ft. It was ultimately decided to sink the well an additional 200ft.

Secondary Batteries.—Commenting on Prof. Armstrong's recent remarks at the Society of Arts, that secondary batteries should be discussed by chemists rather than electricians, *Industries* says, "As electricians have probably more all-round capacity than chemists, it is probable, in spite of Prof. Armstrong, that a pure chemist will do as little as a pure electrician. What is required to study electrolysis successfully is a thorough knowledge of the specialised chemistry needed, and also of electricity and thermo-dynamics. An acquaintance with thermo-dynamics is most essential."

Electric Lighting in Johannesburg.—The Johannesburg *Star* of November 14th contains an interesting account of the electric lighting of the Standard Theatre in that city, and refers to the general adoption of the electric light in Johannesburg. Numerous companies along the Reef have put down electric lighting plants, and a number of private firms have also adopted the electric light. The Standard Theatre installation was superintended by Mr. Sanders, chief of the Electrical and General Engineering Syndicate, who has had considerable experience in the lighting of the Crystal Palace in England.

Breaking Strength of Glass.—Mr. G. W. Plympton, M. Am. Soc. C. E., says the *Engineering and Mining Journal* of New York, has recently made a number of experiments on the breaking strength of glass. The glass used was of Dutch manufacture and varied from ·290in. to ·345in. in thickness; strips of the glass 2in. wide were supported on uprights 18in. apart and loaded at the centre. The bars deflected regularly

Digitized by Google

up to the breaking load, giving no indication of an elastic limit. Applying the formula, breaking load $= \frac{cb\,d^2}{e}$, the average value of the coefficient c was about 3,300lb.

Our Postal Telegraphs.—Some 21 pages of *The Engineer* of December 18th are devoted to an elaborate illustrated account of the Central Telegraph office. "The postal telegraph system of Great Britain and Ireland," says our esteemed contemporary, "is now the most gigantic and complete organisation for the transmission of messages in the world. . . Millions of individuals make use of it, yet a very few outside a small circle possess an adequate acquaintance with the methods and machinery by which so large a portion of the world's work is done." To fill up this vacuum of ignorance is the purpose of our contemporary's most interesting "special number."

The Leeds Electric Tramway.—One of the most severe fogs which has been experienced in the Leeds district for years prevailed there on Monday. A somewhat serious accident on the Roundhay Park Electric Tramway is reported. A car was standing in Harehills-road, where the fog was extremely dense, when another car came along the same line, causing a violent collision. On the stationary car the driver was standing; but, fortunately, there were no passengers. The front of the vehicle was badly smashed. The moving car was only very slightly damaged, and it was about an hour and a-half before the traffic could be resumed, the line being strewn with *débris*.

Electrical Analysis of Milk.—A method for determining the quality of milk by ascertaining its electrical resistance is described in a recent number of the *Chemiker Zeitung*. The idea underlying the process was, in the first place, that a rise in resistance might be expected with increase of fat, and a similar augmentation follow on dilution with water. After the execution of some scores of experiments it was found that an important factor in the fluctuations observed consisted in the nature and quantity of inorganic salts present in the water used for dilution. In order, therefore, to get even approximate accuracy, it is necessary to know the nature and source of the diluent.

Three-Phase Currents and the Telephone Lines.—According to the *Neue Tageblatt* (Stuttgart), the working of the telephone lines between Stuttgart and Heilbronn was considerably interfered with by the experiments carried on on the three phase line between Lauffen and Frankfort after the close of the Exhibition. From tests carried on with the Lahmeyer system at Offenbach, it would appear, however, that the rotary current is much less objectionable in this respect than an alternating current. In this case a telephone line was carried parallel to the rotary current lines and within one yard of them for a distance of six miles, and it was found that conversation could easily be carried on whilst 600 glow lamps were being run off the rotary-current leads.

Belt Formula.—At a recent meeting of the Engineers' Club of Philadelphia, Mr. B. H. Coffey gave the following formula for the horse-power of a driving rope: 1. Neglecting centrifugal force,

$$\text{H.P.} = \frac{V(D^2 + D - 1)}{280},$$

where V = velocity of rope in feet per minute, and D = diameter of rope in inches. 2. Allowing for centrifugal force,

$$\text{H.P.} = V\left\{\frac{2700\,A - W\,V^2}{11{,}180}\right\},$$

where $A = (D^2 + D - 1)$

V = velocity of rope in feet per second, and

W = weight in pounds of rope per foot.

A Surgeon's Transformer.—A handy transformer for surgical purposes has been devised by Dr. Arnold B. Woakes, surgeon to the London Throat Hospital. It is designed to transform an alternating or varying current so as to light a small glow lamp for examinations, to heat a wire for the cautery, or to give "faradaic" shocks. To this end the transformer has three pairs of terminals, marked respectively light, cautery, and shock. An 8 c.-p. incandescent lamp fixed above the apparatus shows when the current is passing through the primary. The strength of the induced current is regulated by varying the position of the primary with respect to the secondary. For the purpose of the cautery a maximum current of 20 amperes at a pressure of 6 volts can be obtained. If a continuous current is supplied to the primary it is interrupted by a special key.

The Arrol Train Approach Indicator.—The distressing accident at Yorkhill, near Glasgow, on September 11th, which resulted in the instantaneous death of five platelayers, who were run over by an unobserved express train, has stimulated the inventive mind of Sir William Arrol to produce an electrical train approach indicator. This consists of a small apparatus, which is temporarily fixed beside one of the rails at a sufficient distance in advance of the point where the road is under repair. An electric bell connected with this apparatus is placed near the men. The wheel tyres of an approaching train depress a spring, and complete a circuit which sets the bell in motion, and so warns the workmen of their danger. The apparatus, which Sir William has not patented, and which costs only about 50s., has been successfully tested on the North British Railway.

Berlin.—In a recent number of the *Elektrotechnische Zeitschrift* is given the following interesting table with regard to supply of current from the Berlin central stations:—

Dates.	16 c.p. lamp-hours (private installations).	16 c.p. lamp-hours (street lighting).	Amp. hours (industrial purposes).
August to December, 1885 ...	635,800	—	—
1886	5,052,024	50,890	—
1887-88 (1½ years)	11,932,000	104,682	—
1888-89	19,563,000	332,674	129,564
1889-90	41,850,000	361,052	695,910
1890-91	59,240,000	363,438	2,744,576

Asbestos Porcelain.—In a recent communication to the Académie des Sciences, M. F. Garros called attention to a new form of porcelain brought out by him. He takes asbestos fibre and reduces it to a fine powder; if pure it exhibits an exceedingly white appearance, but if traces of iron oxide are present there is a slightly yellow tint. In the latter case the oxide is removed by sulphuric or hydrochloric acid. The powder is then made into a paste, moulded into shape, dried slowly, and baked (1200°C.) from 17 to 18 hours. If placed in a very high-temperature furnace, a remarkably-transparent species of porcelain is obtained. This "asbestos porcelain" has already been used for filtration and sterilisation purposes, experiments showing that it is a more rapid and effective filterer than ordinary porcelain, and that the pores are less liable to become clogged up.

Gutta-Percha.—*The Times* of Wednesday contains the following:—"The steamer 'Cachar,' which arrived from Tonquin on Friday at Marseilles, brought back M. Serullaz, who went out two years ago on a mission from the Minister of Posts and Telegraphs, in search of the Isonandra gutta-percha tree in Malaysia. The disappearance of this tree has threatened with great embarrassment, if not with extinction, the submarine cable manufacture. But M. Serullaz has discovered large forests of these trees, and has hit upon practical ways of collecting the gum without destroying the trees as the natives inevitably do. M. Serullaz has been allowed to transport several hundreds of the trees, from ten to fifteen years old, to Algiers, and their cultivation will be attempted also in Guiana. M. Serullaz has left for Algiers with his cargo, which is artificially warmed on board the 'Cachar.'"

Action of Acids on Aluminium.—One of the most cherished beliefs, says *Industries*, concerning this overrated and underrated metal has been that it is not appreciably attacked by nitric and sulphuric acid; and on the strength of this belief its use has been suggested for purposes as diverse as the replacement of platinum in the Grove battery and of cast iron in a nitric acid still. The hopefulness of these suggestions has now been largely discounted by some experiments of M. Leroy, who has shown that aluminium is appreciably soluble in nitric and sulphuric acid of various strengths and different tempera-

Digitized by Google

tures. Nor can this action be ascribed to the presence of hydrochloric acid as an impurity in the commercial acids, as was recently suggested by Mr. Hunt, of the Pittsburg Reduction Company, seeing that the effect of the pure acids does not differ sensibly from that of commercial specimens.

The Roberts-Austen Pyrometer.—At the Cardiff meeting of the British Association, Prof. Roberts-Austen described his new self-recording pyrometer to the Chemical Section. In this instrument, pieces of pure platinum are connected with pieces of platinum containing 10 per cent. of rhodium, and are placed in circuit with a mirror galvanometer. The spot of light falls on a slit, before which a photographic plate passes at a given rate, by which means a curved line is traced, corresponding to the variations in temperature of the heated thermal junction. A similar thermal junction is maintained at a constant temperature by immersion in water. The correctness of the indications are reliable up to the melting point of the platinum employed, within a range of 10 per cent. of possible error, which is accurate enough for most practical purposes. Prof. Roberts-Austen has employed his pyrometer in the investigation of the thermic changes which take place during the cooling of metals and alloys.

The Board of Trade and Overhead Wires.—At the last meeting of the Worcester Watch Committee a communication was received from the Board of Trade, intimating that they had received information of the intention of a private company in Worcester to supply electrical power by overhead wires, and asking the name of the company, in order that the Board might serve a notice requiring conformity to the Board's regulations.—The Town Clerk said the Council had set their face against overhead wires in view of the danger they might be, and had approved a suggestion of putting them underground. It would be unfair if others were to adopt the cheaper method of putting them overhead. It appeared, however, that nothing could be done but to compel the company to put the wires a certain height above the street.—It was suggested that the Town Clerk should inform the Board that the Council knew of no company proposing to supply electricity by overhead wires, and should ask them for a copy of their more recent regulations.

The Electric Launch "Zürich."—The following particulars from *L'Electricien* with regard to the electric launch, "Zürich," which attracted much attention at the recent Frankfort Exhibition, may be of some interest. The launch was constructed by MM. Escher Wyss et Cie., of Zürich, and the Oerlikon Maschinenfabrik. The hull was of steel, and the boat was capable of carrying 100 passengers. The dimensions were :—Length, 53ft.; beam, 10¼; mean draught, 3½ft. The screw, which was 28in. in diameter, was coupled direct to a 10 H.P. two-pole Brown undertype dynamo, and is running at 350 revolutions. Power was supplied by a battery of 56 Schoop 31-plate gelatinous accumulators, having a capacity of 450 ampere hours, and a maximum discharge current of 80 amperes, and weighing in all about 5 tons. The total weight of the electrical equipment was 6½ tons, that of the boat being 15 tons. The motor, when running at 365 revolutions, and absorbing 10 H.P. (102 volts × 75 amperes), propelled the launch at the rate of 8 miles an hour; when only 8 H.P. was absorbed the speed was still 7 miles an hour.

A New Edison Central Station.—The new station of the Edison Electric Illuminating Company, of New York, now in course of construction on Elm-street, will, says the *Electrical World*, embody many new features in central lighting station practice. The entire scheme has been worked out by Mr. J. Van Vleck. His recent trip to Europe, and thorough study of practice over there, resulted in his recommending to his company the adoption of large generators of from 1,000 to 5,000 H.P. It is the intention to use very high steam pressure and new quadruple expansion engines. These, together with the "hot blast" system, an elaborate system of economisers and many other refinements, will give an economy never before attained in engineering practice. Many other things are promised, among which will be the Van Vleck system of "cannon piping." This consists of copper pipe wound with steel wire, and fittings made of gun metal. Mr. Van Vleck is confident that by the arrangements contemplated he will be able to obtain one-horse power from each pound of coal. Among the electrical features will be large Sir William Thomson voltmeters, with dials three feet in diameter, so that the pressure of the system can be read all over the station. The main ampere meters are to be direct-reading instruments on the balance principle. When completed the station will be 160ft. high, and occupy a plot of ground 200 by 100.

Coastal Telegraph Communication.—An important fact has been made known in connection with the recent alarm concerning the safety of H.M.S. "Banterer," says the Plymouth correspondent of *The Times*. Owing to her non-arrival after leaving Queenstown, and in view of the stormy weather, anxiety was manifested as to her safety on Wednesday and Thursday of last week. On Friday afternoon a vessel was prepared for sea to go in search of the "Banterer," when news came that she had been seen passing Clovelly. It has been ascertained, however, that both on Wednesday and Thursday she was observed from Hartland Point Lighthouse, lying at the back of Lundy Island, in the Bristol Channel. The lighthouse keepers, however, did not communicate this fact to the naval authorities, *because the nearest telegraph station to Hartland is four miles distant;* and they were unaware of the concern which was felt for the "Banterer's" safety. Thus a strong illustration is supplied of the necessity for connecting the coastguard stations and lighthouses by wire with the general telegraphic system of the country. If the Hartland Lighthouse keepers had been able to telegraph the whereabouts of the "Banterer," all the fears that were entertained concerning her and the expense of fitting out a vessel to go in search of her would not have occurred. Lundy Island was formerly connected by telegraph cable with the mainland, but the cable was broken nearly two years ago, and the Post Office have never yet been induced to repair it. *The omission to connect Hartland with the telegraph office by wire is the more inexplicable because a telegraph wire runs within five hundred yards of the lighthouse.*

Brighton.—*The Sussex Daily News* has the following very pertinent remarks with regard to the position of electric lighting matters at Brighton :—"The situation is briefly this. The Corporation have for several years been in the enjoyment of authority to supply electricity within the borough, but until September last had not chosen to avail themselves of that authority. They had, nevertheless, used their privileges unmercifully to prevent the Company from attaining such a position as would enable them efficiently to supply the needs of the town. . . . At length the Board of Trade interfered, and refused to allow such an unfair state of things to continue. . . . Driven to bay, the Corporation undertook to exercise their long-neglected powers, and after the utmost possible delay electricity works and mains have been established, and a certain extent of supply has been accomplished. . . . The Corporation mains at present only extend to a very few streets indeed. Undoubtedly they are the most important ones, for they have been carefully selected as likely to prove the most remunerative, and the district which they surround includes very valuable property. But it must be remembered that these half-dozen principal streets do not comprise a tenth or even a twentieth part of the houses within the small district through which they run, and that the area of that district is roughly about a tenth of the whole borough. . . The original estimate of £32,500 has already proved wholly insufficient, and a further expenditure of £8,500 has been determined upon. For this large outlay the general body of ratepayers get no advantage whatever. Not a single public lamp is lighted by electricity, and only about one in a hundred of the ratepayers has the opportunity of obtaining electricity for private purposes. . . . The Company may by no means improbably obtain the authority of the Board of Trade to do what the Corporation will not, or cannot, do. . . . The Council will probably find in time, as has often happened before, that they must make a worse bargain than they have already refused. Meantime, there is every reason to believe that the Company will be very generally supported in the town by those who regard the policy of the Council as wanting in justice."

THE DETERMINATION OF CURRENTS IN ABSOLUTE ELECTRO-MAGNETIC MEASURE.

BY G. F. C. SEARLE, M.A.

(*Continued from page 141.*)

§ 43. **Methods of Finding M.**—Either of the two methods of finding N given in § 36 gives a means of calculating M, since the value of N for either circuit, determined on the supposition that the magnetic force is entirely due to unit current flowing in the second circuit, is identical with M. We shall see examples of both methods a little later.

There is a third method of finding M, depending on the theory that when a current flows in any circuit, a state of motion is set up in the ether around it, and that kinetic energy is stored up in that motion. We saw in § 15 that there was reason to believe that wherever a magnetic force H is acting there is a storage of energy in the medium of amount $H^2/8\pi$ ergs per cubic centimetre. Now, if we have a pair of circuits A, B, carrying currents i, i', each will produce a distribution of magnetic force, and the resultant magnetic force at any point will be the resultant of the magnetic forces due to the two currents separately. If H_1, H_2 are the magnetic forces due to the two currents at any the same point, then since each is a vector and can be represented in direction and magnitude by a straight line, it follows at once, from a well-known result in Trigonometry, that the resultant magnetic force H is given by the equation $H^2 = H_1^2 + H_2^2 + 2 H_1 H_2 \cos\theta$, where θ is the angle between H_1 and H^2. Hence, the part of the store of energy in the field which is due to the coexistence of the two currents is $H_1 H_2 \cos\theta . 1/4\pi$ ergs per cubic centimetre. Integrating this through all space we find that the total amount of what we may term "mutual" energy is $\iiint \frac{H_1 H_2 \cos\theta}{4\pi} dv$ ergs, where dv is an element of volume.

Now, suppose that the current i' is gradually started in B, the current i being maintained constant in A. By Faraday's law of induction an electromotive force is produced in A equal to $M\, di'/dt$ in the opposite direction to the current i. Since this current is kept constant, the batteries or other electromotive agencies in A must be doing work at the rate $i M\, di'/dt$ ergs per second in driving the current against this E.M.F. Hence, the whole amount of work expended by the batteries in A, over and above that spent in heating the wires is $i M \int dt . di'/dt = M i i'$ ergs. Again, since the current in A has been kept steady, the work expended by the batteries in B in establishing the current i', is the same as if there had been no current in A. Where has the $M i i'$ ergs of energy given out by the batteries in A gone to? Sir William Thomson long ago pointed out that it must be stored up somewhere as kinetic energy. We now believe that it is stored in the ether. Equating the energy which the battery in A has sent out into the ether in consequence of starting the current in B, to the part of the store of energy which depends upon the coexistence of the two currents, we obtain

$$M i i' = \frac{1}{4\pi} \iiint H_1 H_2 \cos\theta \, dv.$$

Taking H_1 H_2 as the magnetic forces due to unit current in A and B respectively, we have

$$M = \frac{1}{4\pi} \iiint H_1 H_2 \cos\theta \, dv.$$

Although extremely instructive, this method of determining M is not so practically useful as the first and second methods. It can be very easily applied to the case in which the two coils are long solenoids, one being wound over the other.

These three methods will be found in Maxwell's Paper on "A Dynamical Theory of the Electro-magnetic Field," Royal Society *Transactions*, Vol. CLV., or in Vol. I. of his collected "Scientific Papers."

§ 44. **Mechanical Forces between Currents.**—We have seen (§ 35) that the mutual potential energy of a pair of currents of strength i, i' is $-M i i'$, where M is a quantity which depends upon the geometrical configuration of the two circuits. M can be calculated by Neumann's formula $M = \iint \cos\epsilon \, ds \, ds'/r$. (§ 41), or in other ways. We proved, in § 30, that if the number of lines of induction due to some foreign magnetic system which pass through any circuit is N, then when this circuit carries a current i, it experiences a mechanical force X dynes where $X = i\, dN/dx$, X being measured in the direction in which x increases. But if the magnetic system is a current of strength i', we have $N = M i'$, so that $X = i i'\, dM/dx$ dynes. Thus the first step towards the calculation of the mechanical forces exerted by one circuit on the other is to find the appropriate differential coefficients of M.

Since in this method we deal only with closed circuits, we shall obtain a value for the mechanical force, free from any indeterminateness or uncertainty. It is indeed possible to assign laws of the action of an element of one current upon an element of another current, but we cannot prove them experimentally since we can only deal with closed circuits, and the various laws all give the same result when applied to closed circuits. We shall explain briefly two of these laws, taking the law of Ampère, because it was the first which was developed, and the law of M. Reynard, because it follows very easily from the results we have already obtained.

§ 45. **Ampère's Law.**—Ampère was the first to make an attempt to determine the action of one element upon another. He made many experiments upon the mutual action of a pair of currents, devising several ingenious pieces of apparatus for this purpose. Living as he did in the days of "Action at a Distance," he was unable to imagine that the action between a pair of elements could be other than an attraction or repulsion along the straight line joining them, or that the forces experienced by the two elements could be unequal. He, therefore, determined what law of action between a pair of elements would make the forces experienced by the two elements equal and opposite and directed along the straight line joining them, and at the same time give results agreeing with his experiments when applied to closed circuits. The result of his work was to show that one element *attracted* any other with a force $i i' (2\cos\epsilon - 3\cos\theta\cos\theta')\, ds\, ds'/r^2$, where ϵ is the angle between the directions of ds and ds', and θ, θ' are the angles made by r with ds and ds' respectively. According to this formula, two elements, parallel to each other, and both perpendicular to the radius r, attract each other with a force $2\, i i'\, ds\, ds'/r^2$, since $\theta = \theta = \pi/2$ and $\epsilon = 0$. Again, for two elements in the same straight line $\theta = \theta' = \epsilon = 0$, and therefore the attraction is $i i' (2-3)\, ds\, ds'/r^2 = -i i'\, ds\, ds'/r^2$, the negative sign indicating repulsion. The experiment which was thought to be confirmatory of this result has been shown by Maxwell to be capable of a quite different explanation. See Maxwell, Vol. II., § 687.

Ampère's result can be obtained from Neumann's formula in the following way. If E be the potential energy of a pair of closed currents, then $E = -i i' \iint \cos\epsilon \, ds\, ds'/r$. Keeping one of the circuits fixed, alter the position of the other in any way and calculate the increase in the potential energy. An application of the Calculus of Variations shows that if δE is the increase in E, and δr the increase in the radius r, joining any pair of elements, then

$$\delta E = i i' \iint \frac{(2\cos\epsilon - 3\cos\theta\cos\theta')}{r^2} ds\, ds'\, \delta r.$$

But if each element had attracted any other with a force $i i'\, ds\, ds'\, (2\cos\epsilon - 3\cos\theta\cos\theta')/r^2$, the work spent upon the elements in separating them still further by the distance δr, and therefore the increase in their potential energy would have been $i i'\, ds\, ds'\, \delta r\, (2\cos\epsilon - 3\cos\theta\cos\theta')/r^2$. When we take account of all the elements in both circuits, we obtain the same result as that deduced from Neumann's formula. Thus, if it is any pleasure to us, we may suppose that each element attracts every other one, according to Ampère's law. No one will ever be able to prove that our supposition is wrong; but, on the other hand, we shall never be able to prove that it is right. The method of deducing Ampère's law from Neumann's

Digitized by Google

formula will be found in Prof. Chrystal's article, "Electricity," in the "Encyclopædia Britannica," p. 70.

§ 46. **Reynard's Law.**—We have seen in § 32 that any element ds carrying a current i may be regarded as producing at any point a magnetic force $i\,ds \sin\theta \,.\, 1/r^2$, where r is the distance of the point from ds and θ the angle between r and ds. Since we are dealing with air, this is also the value of the magnetic induction. The direction of the magnetic induction is at right angles to the plane of r and ds. Again, in § 31 we proved that any element ds' carrying a current i' when subjected to the action of magnetic induction B experiences a force $\mathsf{B}\,i'\,ds' \sin\phi$ at right angles to the plane of B and ds', ϕ being the angle between the positive directions of B and ds'. If we suppose that B is due to the element ds, then B is at right angles to the plane of r and ds—*i.e.*, is along the normal to that plane. Suppose now that the second element $i'\,ds'$ makes an angle ϕ with this normal, then, if we combine the two laws mentioned above, we find that we may regard the element $i\,ds$ as exerting upon the element $i'\,ds'$ a force $i\,ds \sin\theta \,.\, 1/r^2 \times i'\,ds' \sin\phi = ii'\,ds\,ds' \sin\theta \sin\phi \,.\, 1/r^2$ at right angles to the plane containing the normal and the element $i'\,ds'$. This direction lies in the plane of r and ds at right angles to the projection of ds' upon this plane.

The direction of this force for varying inclinations of r to the projection of ds' is, perhaps, most easily understood from Fig. 41. All the lines here are supposed to be in the plane of

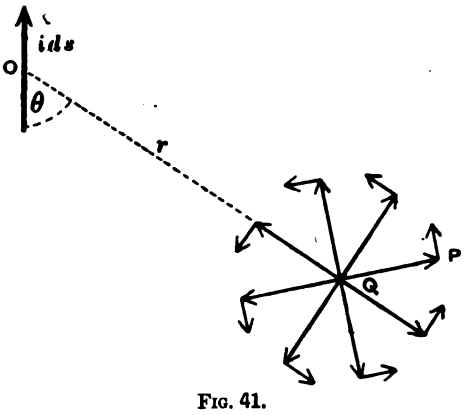

FIG. 41.

the paper which is the plane of r and ds. Q is the centre of the element ds', and Q P is the projection of its direction upon the plane of r and ds. The small arrow at the end of Q P indicates the direction of the force experienced by ds'. Only in the case in which Q P is at right angles to O Q does the direction of the force pass through ds. The inclination of ds' to the plane of r and ds only affects the *amount* of the force; the *direction* of the force depends upon the inclination of r to the projection of ds' upon that plane. It is easily seen that the force exerted by ds' upon ds is in general neither equal to that exerted by ds upon ds' nor in the same direction.

We will now find the force experienced by ds' according to Reynard's law in the two cases which we have already investigated by Ampère's law. In the first case we have $\theta = \phi = \pi/2$, so that the force is $ii'\,ds\,ds' \,.\, 1/r^2$, and is an attraction along r. This result is one-half of that given by Ampère's law. In the second case, $\theta = 0$, $\phi = \pi/2$, and the force vanishes, while Ampère's law gave a repulsion. Thus these two laws give entirely discordant results when applied to elements, although they agree when applied to two closed circuits. An account of Reynard's formula will be found in "Mascart and Joubert," English edition, Vol. I., § 476. Both in "Maxwell" and in "Mascart and Joubert" will be found accounts of some other theories which have been proposed for the law of inter-action of two elements.

We shall now leave the subject of "elements," and pass on to the determination of the value of the coefficient of mutual induction for a pair of circuits. Practically the only shape of circuit which is employed is circular, so that we shall confine ourselves to circuits of this form,

(To be continued.)

A THERMO-ELECTRIC STANDARD OF ELECTRO-MOTIVE FORCE.*

BY HENRI BAGARD.

It has already been proposed to employ thermo-electric couples as standards of electromotive force; but those made use of hitherto being composed of two metals, the electromotive forces obtained have been extremely small and varied with each sample of metal. I sought to determine whether a thermo-electric couple composed of two liquids, that is to say, of two bodies having an invariable structure, possessed, for any two temperatures of their contact surfaces, a well-defined electromotive force. By taking, as my liquids, an amalgam of zinc, containing ·0005 of zinc to 1 of mercury, and a saturated solution of sulphate of zinc (0deg.), I obtained a considerable electromotive force, the couple being non-polarisable.

I dissolve the zinc in the mercury under a layer of sulphate of zinc, which prevents oxidation, and which I remove rapidly at the moment of using the amalgam by means of a piece of blotting paper. The apparatus is constructed in the following manner:—Three tubes, A B C, closed at the bottom, contain the amalgam and sulphate of zinc super-imposed. Tube A is brought to the boiling point of water at atmospheric pressure, a temperature which I will denote by T. Tubes B and C are kept in melting ice. The sulphate of A communicates with that of B by a syphon filled with that liquid. In the same way the amalgams of A and C are connected by a syphon filled with amalgam. Two insulated platinum electrodes plunge into the amalgams B and C, between which there exists consequently only the thermo-electric difference of potential. The sulphate which covers the amalgam C is merely intended to protect it against the effects of contact with the air. The sulphate A is covered by a layer of paraffin to prevent evaporation. In this couple the hot amalgam is the positive pole to the external circuit.

Several couples, separately prepared and compared with one another on different dates, always gave the same electromotive force—about ·0001 volt—and remained non-polarisable. This couple may, therefore, be used as a standard.

I investigated the action of the couple when one of the surfaces in contact was kept at 0deg., and the other at a temperature t, varying between 0deg. and T. Here are some of the numbers obtained, T being 99·3deg.:—

t	15·7°	33·6°	40·7°	48·6°	54·3°
$f(t) = E_0^t/E_0^T$.	·148	·320	·392	·470	·528

Taking T = 99·3deg., the function $f(t)$ is exactly represented by the two-term formula

$$(1.)\quad f(t) = ·0093\,t + ·00000774\,t^2.$$

Thus the representative curve is, as in most instances of bi-metallic couples, a parabola, and the curve turns its convexity towards the line of temperatures.

I next measured in absolute measure by means of a capillary electrometer sensitive to $\frac{1}{10000}$ of a volt, the E.M.F. force E_0^T of the standard couple, by compensation with the difference of potential produced at the ends of a resistance equal to the legal ohm, by a suitable current the value of which I determined by the electrolysis of nitrate of silver, I arrived at a mean of several determinations and making use of the formula (1)

$$E_0^{100} = ·1167 \text{ volt},$$

the error to be feared being of the order of ·0001 volt. The value of E_0^{100} is, therefore, about one hundred times greater for the couple under investigation than for an iron copper couple which gives about ·0011 volt. Bringing the value of E_0^{100} into the first equation, we obtain the following expression for the E.M.F. for temperatures between 0deg. and 100deg.

$$(2.)\quad E_0^t = ·001077\,t + ·0000009\,t^2.$$

To determine the influence of the richness of the amalgam in zinc, I compared couples containing different amalgams with

* *Comptes Rendus*, Vol. CXIII., No. 24.

Digitized by Google

the standard couple by the method of opposition already employed. When the proportion of zinc is less than ·00005 the couple polarises. With larger proportions the couple becomes non-polarisable, and the E.M.F. decreases continuously as the amount of zinc increases, as is shown by the following table:—

Weight of zinc to 1 of mercury...	·00025	·00035	·00045	·0005	·00055	·00075
E_0^{100}	·1197	·1183	·1171	·1167	·1164	·115

To sum up. The couple I have investigated is absolutely constant between two given temperatures; it can be used on closed circuit without polarising, and its E.M.F. for temperatures between 0^0 and t^0 is given by formula (2). Finally, it is not necessary to weigh the zinc to be dissolved in a given weight of mercury with great precision, since the above table shows that the variation of E_0^{100} does not amount to ·0001 when the proportion of zinc varies by ·00001, or $\frac{1}{10}$th. This research was carried out in the Physical Laboratory at Nancy.

THE FRANKFORT EXHIBITION.—XVIII.

(FROM OUR SPECIAL CORRESPONDENT.)

Reference has several times been made in these articles to the fine show made by the "Helios" Company, of Cologne. Their chief exhibit was a 600 H.P. alternator, driven direct by a horizontal steam engine by Paucksch, of Landsberg. The steam engine was compound with jet condensation, and provided with expansion gear of the Armington and Sims type. An engine of this description takes up a good deal of room, but this is perhaps compensated for by the ease with which the moving parts can be got at and examined while it is at work. As regards the dynamo, it is of the same type as that described on p. 37 of your issue of November 13th, where the "Helios" method of switching alternators in and out of circuit is also explained and illustrated.

The core of the "Helios" transformer (for illustration see *Electrician*, November 13th, p. 38) is built up of E-shaped stampings, 20mils. thick, and carefully insulated from each other. The dimensions and quality of the iron are such that, in the 10 kilowatt transformer only 180 watts, and in the 5 kilowatt transformer only 110 watts, are wasted by hysteresis the frequency being 50∿ per second. The primary coils are wound on fibre bobbins ·4in. thick. Sheets of this fibre only 1mm. thick are able to stand pressures of about 10,000 volts. The secondary coils are wound on bobbins of the same material, and are composed of copper strip.

Amongst the continuous-current machines exhibited by this firm a very compactly-built 22 kilowatt dynamo, coupled direct to a Dingler engine, was particularly noticeable. (*See* figure.) At 450 revolutions it had an output of 110 volts and 200 amperes, and was chiefly used for accumulator charging and for providing exciting current for the large alternator. The field-magnets were built up of thin iron strips. All the "Helios" dynamos are built with self-oiling bearings by means of rings, the firm being the first in Germany to apply this system to dynamos.

TRANSFORMER SUB-STATIONS AND THE LAW.

The spectacle of a brave man struggling with adversity is said to be a particularly pleasing spectacle to the gods; and if, for the purposes of the proverb, the term man includes limited liability company, the career of the London Electric Supply Corporation since it first commenced operations under its old title of Sir COUTTS LINDSAY and Co. some six or seven years ago, must have been a never-failing source of satisfaction to these sublime gentry. Even the early successes of this bold enterprise proved its bane. Inaugurated in a modest manner in a Bond-street cellar, the demand for current grew so rapidly that before long both staff and plant were being over-worked, with the inevitable result of frequent breakdowns. Threats of injunctions also soon became unpleasantly numerous. It was, therefore, with something akin to relief that all who wished well to these pioneers of central-station lighting and alternate currents heard of the formation of a big company with a big capital, and the proposed erection of a huge generating station at Deptford. But the gods, apparently, were not disposed to forego their favourite amusement. At one of the very first meetings of the then new Company on December 21st, 1888, the Earl of CRAWFORD had to report that the building work had been thrown back "owing to the excessively bad summer and the rainy weather," and that some two months had been lost. When Deptford finally was ready to supply current the mains to take it were not ready, and at the meeting of the shareholders at the end of March, 1890, Mr. FERRANTI regretted to say that the temporary mains had proved "a very great failure," and, consequently, that only one-fourth of the output of the Deptford dynamos was available. Then, in November of last year, the demon of mischief surpassed himself by the burning out of the temporary transformer sub-station at the Grosvenor Gallery, which resulted in a three-months' suspension of the supply. And now Mr. Justice KEKEWICH has been moved to grant an njunction restraining the Lond on Electric Supply Corporation from using the buildings and cellars belonging to them in New Bond-street as a converting and distributing station, or otherwise, so as to occasion a nuisance to Messrs. SAVORY and MOORE.

Digitized by Google

The daily papers, so far as we have seen them, cite this action of "Savory and Moore *v.* the London Electric Supply Corporation" as an illustration of the great danger arising from the erection of electric light supply works in the heart of a city, in contiguity with other buildings. This alarmist view of the case may, perhaps, be excused since the plaintiffs talked of electric cables and step-down transformers of such a highly inflammable and combustible nature that even with the greatest precautions, both in the construction of the buildings containing them and in the mode of carrying on the business of distribution, there was a great risk of fire. It is, however, somewhat difficult for the lay mind to see the full force of the reasons upon which Mr. Justice KEKEWICH based his decision. It was, he said, clear beyond dispute that there was now no imminent danger against which the plaintiffs were entitled to protection; but since it did not appear what use was going to be made of the rest of the building other than the cellar, or that danger of fire had been completely obviated, he granted the injunction asked for. "The powers and therefore the dangers of electricity," the learned Judge is of opinion, "cannot be regarded as known even by scientific men with sufficient accuracy to justify a positive statement respecting possible results under hypothetical circumstances, especially when the locality is in the heart of a crowded city."

Our utter ignorance of the nature of electricity cannot, of course, be disputed for one moment. But this and much more may be conceded without in any way admitting that a properly constructed, properly managed alternate-current transformer sub-station constitutes a danger to the community half so grave as those huge cumuli of wood which are dotted about all over London, or those stores of "spirit tinctures and other spirituous preparations," such as are kept by Messrs, SAVORY and MOORE themselves, and which the defendants, with grim humour, insisted were a source of considerable danger to their distributing centre. An electric light supply station with its whirling armatures, high-speed engines, and high-pressure boilers, might, perhaps—its comparative harmlessness notwithstanding—be considered by the judicial mind as too risky to form a feature of a populous district. But a transformer sub-station, even if "extra high-pressure" currents all the way from Deptford are led into it, can with a moderate expenditure of money and constructive skill be made absolutely innocuous. A fireproof compartment not so very much larger than a respectable strong room would hold transformers and manipulatory apparatus sufficient to supply an entire district. Cables need not be "highly inflammable" nor switches "highly combustible;" and in this way, while the chances of fire can be reduced to a minimum, its area can at the same time be strictly limited. The disastrous fire of November 20, 1890, which gave rise to the present action, occurred in a temporary receptacle at a moment when everything was favourable to a big blaze. Precautions have since been adopted which were satisfactory to the Court; but "the defendants' plans above the basement wanting in precision, and a disposition to be guided by circumstances, and the exigencies of trade" being "an awkward factor in the sum of possible results," the Grosvenor Gallery transformer sub-station will have to go, unless the Corporation climbs down and is allowed to give an undertaking, on appeal, that the upper part of the building will not be used for "dangerous" purposes. Although this decision may not be a very serious matter for the London Electric Supply Corporation with its Trafalgar-square and Victoria sub-stations to fall back upon, it may prove an unwelcome addition to the many dis-services rendered by fate to the cause of electrical distribution by means of alternate currents.

REVIEWS.

Les Électro-thermo-cautères. Par le Dr. CHEVAL. Extrait du *Journal de Médecine, de Chirurgie et de Pharmacologie de Bruxelles.* (Brussels: October, 1891.)

In this pamphlet, which we have received from the editor of the *Journal of Medicine and Surgery* of Brussels, the author discusses the problems of heating surgical cautery wires. Although the galvano-cautery has been long employed in surgery, it is only in recent years that its use has become common. At present we believe that few of those who are engaged in active surgical practice are without an apparatus of some kind for galvano-cautery. This is due partly to modern improvements in primary batteries, and partly to the general introduction of accumulators.

Dr. Cheval has a strong preference for this latter source of current, and for use in the consulting-room no doubt an accumulator is very convenient; but when the cautery operation has to be performed at the house of a patient the weight and bulk of accumulators become a serious objection to their use. And it is in such cases where the cautery has to be taken to the patient that the real difficulties of the matter begin, especially if large cauteries, demanding 40, 50, or 60 amperes, have to be heated. We are not so sure that primary batteries have as yet been superseded for all surgical cautery purposes. In most cases comparatively thin platinum wires are employed, needing only 10 or 15 amperes to heat them; and this can be done quite well with some of the modern types of portable sealed batteries, coupled up in parallel, at less cost in weight and bulk than that of an accumulator, and with the additional advantage that all risk of accident through upsetting of corrosive liquids is avoided. It is not impossible for an open battery to come to grief at the last minute; and we shudder to think of the consequences if, after the hour of operation has been fixed, assistants engaged, and nurses provided, there should occur some unfortunate jerk or accident to the battery, spilling the corrosive liquids and throwing the battery out of gear, and perhaps ruining the clothes and the temper of the operator. The bichromate batteries, which are so much in favour with medical men, are at all times rather awkward to carry about, and are very unsatisfactory in several ways. Many of our readers are, no doubt, familiar with the instrument makers' cautery batteries of bichromate type, with rows of plates of zinc and carbon in each cell, the whole enclosed in a polished mahogany box, which effectually conceals the condition of the battery connections inside; but it is not everyone who can realise the perpetual worry and annoyance of such a thing, nor the cost of having it kept in order. At the present time, however, those who have rebelled against the tyranny of the bichromate battery can make use of the improved type of chloride of silver cell, which is sealed up, small and fairly convenient; or they may find what they require in one of the more modern dry batteries. Either of these forms of battery are suitable for cautery wires requiring up to 15 or 20 amperes of current to heat them. At the same time we think that the best possible form has not yet been attained for surgical cautery purposes, and that something might yet be devised of the dry battery type, with large flat plates, something after the plan of Volta's original pile, but with means for connecting them in parallel. Such an arrangement should be possible with an internal resistance low enough for it to yield as much current as would be wanted for cautery purposes, at least for the short periods of time during which a cautery requires to be heated. The liability to polarisation could hardly be a serious objection, seeing that the wire is rarely used for more than thirty seconds at each operation. There are not many cauteries which absorb so much as 40 or 50 amperes, though we have heard of one or two giants needing 60 amperes, which give considerable anxiety to those who are responsible for raising them to the required heat.

There is one point which Dr. Cheval has not alluded to in his paper, but which we think is of great importance, and that is the damage likely to be done to an accumulator if it be discharged at an excessive rate through a big cautery of low resistance. This is a point which is not thoroughly appreciated by medical men, if we may judge from a row of accumulators

Digitized by Google

which we lately saw in the shop of an instrument maker; to all appearance they seemed new and good, but every one of them had been totally spoiled by the trying nature of the work to which they had been put.

The writer of the pamphlet very properly insists upon the importance of having proper leads, and handles of suitable dimensions for cauteries. In fact, instrument makers and medical men might very well pay a little more attention to these points, and to the matter of securing better contacts in their instruments. We have seen the gutta percha insulation melted off a thin copper wire which was being used to carry the current to a large cautery.

Dr. Cheval next leads up to what is perhaps the most important part of his paper, namely, that iron wire is better than platinum for cautery purposes. He quotes the experiments of Preece on the number of amperes necessary for heating to redness wires of different metals. Preece found that for wires one millimetre in diameter platinum required 40 amperes, and iron 24 amperes. This gives a considerable advantage to iron; and an additional advantage is claimed for it by Dr. Cheval, because with iron wires the rise of resistance with increased temperature is greater than with platinum. It seems to us, however, that here our writer is trying to prove too much; we think Mr. Preece's figures have already included the advantages gained in this way for the iron wire. The great difference between 24 amperes and 40 amperes would not be expected from the specific resistances of the two metals at ordinary temperatures; for these are 9·82 and 9·15 respectively, and the superiority of iron over platinum for cautery purposes must be due to the difference of their specific resistances at a red heat. The specific heats of the two metals (·112 for iron and ·032 for platinum) differ considerably, but the results are but little influenced thereby.

Dr. Cheval says that he found, after replacing his platinum wires by iron, that cauteries which had required from 15 to 25 amperes when made with platinum were perfectly heated with a current of from 7 to 12 amperes when iron was used. Nor was that the only advantage gained; for he found that his cautery handles, which could hardly convey the large currents needed for the platinum wire without serious loss from heating, were able to do so perfectly for the iron.

He also satisfied himself that no bad effects need be feared from the use of iron wire through oxidation, or through portions of iron rust being left entangled in the tissues of the wound; and he declares that he has never had any sort of accident with iron wire, nor has he seen any, though he has witnessed the operations "thousands and thousands of times." This, perhaps, is hyperbole, but, at any rate, his experiences seem to be satisfactory.

Moreover, by the ingenious plan of using silvered iron wires, he claims to have been able to prevent oxidation from taking place, and so to protect the wire without affecting its efficiency.

If these results should be confirmed by independent trials in this country the introduction of his methods ought to receive attention at the hands of surgeons and instrument makers here. By the use of silvered iron wire instead of platinum surgeons would gain in all the following points:—(1) Increased ease in heating their cauteries, with a corresponding saving in the bulk of their battery plant; (2) a firmer and stiffer cautery instrument; (3) the instrument would be cheaper.

The remainder of Dr. Cheval's pamphlet is taken up with a description of his installation of 25 accumulators, and of his methods of regulating the current by rheostats and so forth. There is nothing of any particular interest or novelty in this portion of the essay. He also describes a plan for utilising the electric lighting current of the town mains for medical applications, from which we infer that his district is served by a continuous current; but we believe that few medical men would care to run the risks of using a 100-volt current for treating their patients, unless the connections were permanently arranged with a considerable resistance always in circuit; and we feel sure that no patients would willingly put themselves into such a circuit if they knew that so slight a mistake as a plug-key put into the wrong plug-hole, or some other slight error with the resistance coils, might give them such a dose of the remedy as they would be likely to remember for some time.

THE PRINCIPLES OF ALTERNATE CURRENT MEASUREMENT.

BY HUGH ERAT HARRISON, B.SC.

(*Continued from page 171.*)

The Board of Trade, however, authorises the use of "instruments constructed on the principle of the balance, in which, by proper disposition of conductors, forces of attraction and repulsion are produced, which depend upon the amount of current passing, and are balanced by known weights . . . for the measurement of current whether unvarying or alternating."*

In Fig. 6 is shown a diagram of an electric balance. AA', BB' are two pairs of fixed coils; between them is suspended about a horizontal axis PQ, like the beam of a balance, a third pair of coils MM'. If a current passes through the instrument, as indicated by the arrows, bobbin M is pulled and pushed downwards, while M' is pushed and pulled upwards; the beam is then brought back into the position of equilibrium, which it has when no current passes, by putting weights into a pan S; but to obtain more perfect adjustment, riders, similar to those used on a chemical balance, are also employed, though not indicated in the diagram.

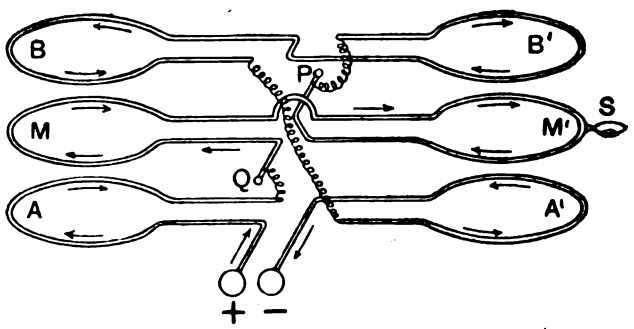

FIG. 6.

In this instrument the forces of attraction and repulsion, with which the conductors carrying the current act on one another, are balanced by the force of gravity acting on the weights, and are thus measured. If the position of two conductors relatively to each other is fixed, the force which they exert on each other is equal to the product of the currents flowing in them multiplied by some constant. But in the case of the balance sketched the same current passes through all the conductors, and as a reading is only taken when the beam has been forced back into its original position, the force necessary to do so is proportional to the *square of the current* flowing.

To determine this constant it is only necessary to put the instrument in series with a silver voltameter and send an unvarying current through the two. If C is the current, as shown by the voltameter, w the weight necessary to bring the beam to its zero position, and k the unknown constant: $-w = kC^2$, hence $k = w/C^2$, k being now determined the value of any current can be calculated by the formula $C = \sqrt{w/k}$.

It is of the utmost importance to note that, while an unvarying current may be measured by means of the balance or the voltameter, neither of these instruments measures currents directly.

The voltameter records the fact that during the time t, a quantity of electricity Q, has passed through it, and the current is calculated from these data by the formula $C = Q/t$. The weights used to adjust the balance indicate not the current, but the *square of the current*, and the current is calculated by means of the obvious formula $C = \sqrt{C^2}$.

These instruments measure, therefore, two totally distinct functions of the current; but if they are both used to determine the same unvarying current, the two values of the current, as calculated by the above formulæ from the data, respectively observed in the two cases, are identical. It is, however, necessary to investigate this question when currents other than unvarying are measured.

* For the description of Sir William Thomson's balances, see *The Electrician*, vol. XXI., p. 368.

Digitized by Google

An undulatory current which flows in one direction, like that drawn in Fig. 4, can obviously be measured by a voltameter or a balance, and such a current will now be considered. It will probably, however, be simpler for the non-mathematical if, instead of choosing a current which is always changing, a current which changes suddenly and remains constant for an appreciable interval of time, like that described in Fig. 7, be taken.

Tenths of seconds are marked off on the line O T. These are not drawn strictly to scale in the figure, as it would make it inconveniently narrow. The current is 5 amperes to begin with, and remains constant for 0·1 second; for the second 0·1 of a second it is 11, for the third and fourth 19, for the fifth 11, and the sixth 5, when a fresh cycle commences.

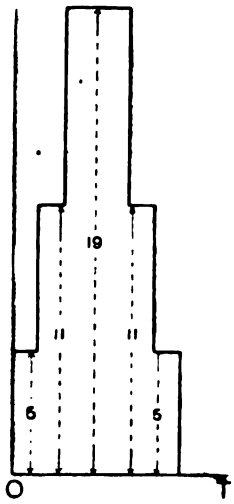

Fig. 7.

If the voltameter is left in the circuit 0·6 of a second, the total quantity of electricity that has passed through it is shown by the area included to be $0·5+1·1+1·9+1·9+1·1+0·5=7·0$, since the current in each case remains constant for one-tenth of a second. The voltameter is in circuit for six-tenths of a second, hence the average quantity which passes per second is $7·0/0·6=11·7$ nearly. Or to put the matter in words, the significance of which will be pointed out shortly,

(*a*) *The time average of the strength of the current at each instant in amperes is*:—

$$\frac{(5\times0·1)+(11\times0·1)+(19\times0·2)+(11\times0·1)+(5\times0·1)}{0·6}$$

$=11·7$ nearly.

Now suppose the same current to be sent through a balance; during successive tenths of a second the beam will be acted upon by forces proportional, not to the strength of the current at each instant, but to the square of the strength at each instant. If f is the force which one ampere could exert, the beam now experiences the forces $f\times5^2$, $f\times11^2$, and $f\times19^2$ succeeding each other at intervals of one-tenth of a second. The average force or time average of the force by which the beam is acted upon is—$0·1f(5^2+11^2+19^2\times2+11^2+5^2)\div0·6=169f$.

The beam is too heavy to pulsate appreciably with the rapidly varying force produced by the current, and can therefore be kept in position by a weight.

A current of one ampere produces the force f; if, then, C is the unvarying current which would produce the force $169f$; $C^2f=169f$, therefore $C=\sqrt{169}=13$; or, expressing matters in the language used in the case of the voltameter measurement,

(*b*) *The square root of the time average of the square of the strength of the current at each instant in amperes is*:—

$$\sqrt{\frac{(5^2\times0·1)+(11^2\times0·1)+(19^2\times0·2)+(11^2\times0·1)+(5^2\times0·1)}{0·6.}}$$

$$=\sqrt{\frac{101·4}{0·6}}=13.$$

The values of this varying current, expressed in terms of the corresponding unvarying current, as deduced from data got from the voltameter and the balance, are 11·7 and 13 respectively. The case supposed is not, it is true, one likely to occur in practice, but it has served the object of showing, in an elementary and unmistakable way, that with a varying current the two methods of measurement must give different results, and that the difference may be very great indeed.

If the current shown in Fig. 4 had been taken and the voltameter had indicated a current of 1 ampere, the balance would have indicated a current of 1·11 amperes.

A glance at Fig. 6 shows that the indication of the balance is independent of the direction in which the current is sent through it; it can, therefore, be used for an alternating current with which, unlike the voltameter, its readings will be the same before as after commutation. As the commutation of an alternating current to make it flow always in the same direction is rarely possible, such currents can, as a rule, only be measured by means of some form of balance.

The legal meaning of the word "ampere" is thus indeterminate except in two cases, those of the unvarying current and of the alternating current.

There are really two amperes, an electro-chemical ampere and an electro-dynamic ampere; call these for the moment the (*c*)-ampere and the (*d*)-ampere respectively.

An unvarying current can be measured equally well by either, as the number expressing the value of the current is the same in both cases. An alternating current measured in (*c*)-amperes would always have the value zero, it is therefore measured in (*d*)-amperes.

An unvarying current may be imagined to begin varying a little, and these variations to increase until it developes into an alternating current. The ratios of the values of this current, as measured by the two methods, vary from 1:1 to 1:∞, and unless the curve representing the value of the current at each instant in amperes be known, for about the instantaneous value of the current there is no ambiguity, the true ratio cannot be determined except by actual measurement. This state of affairs is unsatisfactory, and may prove very inconvenient.

A new kind of ampere having been introduced, it is interesting to speculate what new kind of meaning may be attached to the word "coulomb."

It has been said, when speaking of the unvarying current, that a coulomb is as definite a quantity of electricity as 1lb. of water is of water; a current in a conductor has been conceived to be a carrying of electricity across a section of that conductor, so that the value of a current may be taken to mean the quantity of electricity carried across the section in a given time. Simple and definite as this may seem, its interpretation, if applied to the alternating current, really depends upon how far the reader's mind is influenced by mathematical conventions.

A simple example may show this to be the case. When an Exhibition is open it is customary to publish a statement of the number of people that have passed the turnstiles each day; if an individual leaves the Exhibition and comes in again on the same day, he is reckoned as two people passing in; with this definition it is quite clear what is meant by 10,000 people having passed the turnstiles. But there is another way of looking at the matter. The direction in which a person crosses a turnstile to go in is the exact opposite of that he takes to go out. If the *direction in* is reckoned + and the *direction out* is reckoned −, since everybody who passes in after the opening of the Exhibition in the morning must pass out before the closing in the evening, the total number of people that would pass the turnstiles on the day in question is 0.

Two statements, therefore, to record the measurement of a well-understood physical phenomenon may be 10,000, or 0, the proper number depending simply upon definition.

Returning now to the alternating current shown in Fig. 3, it is uncertain, without knowing the convention sanctioned by authority, whether it conveys, say, 10 coulombs per second across any section of the conductor or 0 coulomb. Suppose, however, the current commutated, and measured by the voltameter to be 10, on the balance it will be over 11. Do then 10 or 11 coulombs pass per second?

This seems very much like asking—if water flows in an unvarying stream over the top of a weir, but breaks into drops so

Digitized by Google

as to flow into the river below in an intermittent current—can two tons of water flow into the stream below for every one ton that flows over the top of the weir?

From a legal point of view such questions cannot be answered until further definitions have been furnished by the Board* of Trade. The difficulty may or may not be a grave one, the question has rather been raised to show the importance of the method of measurement employed, in any case, being stated now that the ampere has at least two meanings.

Much greater difficulties, however, than those of mere definition arise from effects produced in certain circuits, when carrying, varying, or alternating currents, due to the property known as self-induction, which must be considered at some length.

[ERRATUM.—In the references to Fig. 5 of this article on p. 171 of our last issue, for M T read L O.]

(To be continued.)

WELDING BY THE ELECTRIC ARC.

The Benardos system of electric welding consists, as many of our readers are aware, in the use of an electric arc formed between the metal to be operated upon, and a carbon manipulated by the workman. As originally used and described,* the process did not appear to be very promising. It might be thought that an arc would be a difficult tool to handle, and the accounts of early experiments seemed to suggest that its usefulness would be confined to the repair of large pieces of work. The arc system of welding has, however, received the careful attention of Messrs. Lloyd and Lloyd, of Coombs Wood Works, Halesowen, near Birmingham. This firm are the largest manufacturers in Europe of butt-welded, galvanised, wrought-iron gas, steam, water tubes and fittings. It may be mentioned that they stock about 200 miles of finished tubes, and the manufacture of ten miles a day is an ordinary rate.

The history of the application of the Benardos process to this manufacture is interesting. Messrs. Lloyd and Lloyd were the first to introduce the system of gas welding for the manufacture of large iron tubes, the metal being heated locally by a

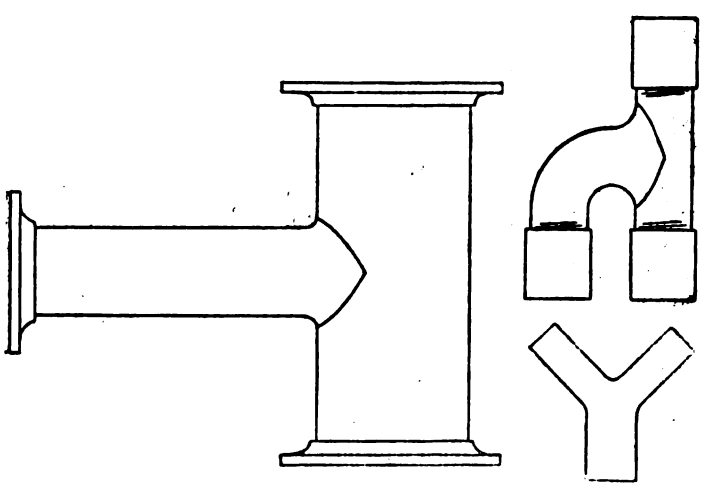

FIG. 1.—Samples of Fittings made by Electric Welding.

powerful blow-pipe. This mode of heating the metal allows a local application of the heat which is impossible upon a smith's hearth, and also permits much thinner and larger pieces to be handled. In fittings, that is to say, bends, tees, and elbows, &c., this is particularly noticeable. A diameter of six inches used to be the limit for wrought-iron work, and even these could only be made by a few highly skilled workmen. Larger sizes could only be produced, at an almost prohibitive cost, from iron of $\frac{5}{8}$ or $\frac{3}{4}$ thickness. By the electric process, fittings of 12 in. diameter $\frac{5}{16}$ thick, have been successfully made and tested to 800lbs. per square inch.

* *The Electrician*, Vol. XX., p. 58.

The process of arc-welding resembles soldering in some respects, but it is essentially the same as that of "burning-on," with two important differences, viz., that instead of relying on the heat contained in a quantity of molten metal, which is but a poor vehicle seeing its low specific heat, a continuous application of heat from a never-failing source is provided; and this heat is in the most efficient form, since it is at the highest temperature known to science. The simple "burning-on" process is rarely used except for the repair of castings. The gas-welding process made it possible to work thin metal, the patented process of gas-welding of Messrs. Lloyd and Lloyd being used under license for the manufacture of corrugated flues. So similar is the electric arc process, that but for the intense light and fragrant smell of ozone it would be easy for any intelligent spectator to mistake the simple carbon-holder for a blow-pipe, and the roaring arc for a blow-pipe flame which appears to shoot out to the work.

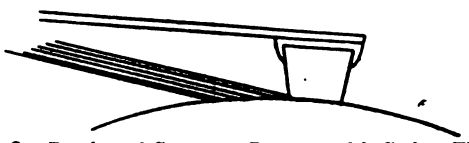

FIG. 2.—Brushes of Crompton Dynamo with Carbon Tip.

A compound Davey-Paxman horizontal engine 12¾in. and 20in. × 24in., giving 100 I.H.P. at 100 revolutions per minute, is employed to drive three Crompton dynamos of the ordinary pattern. These are respectively marked 140 volts 150 amperes, 150 volts 200 amperes, and 150 volts 200 amperes. They run continuously during working hours, and, but for the higher voltage, differ in no way from Messrs. Crompton and Co.'s ordinary patterns. Carbon-tipped brushes (Fig. 2) are used, as in several central-station dynamos of this make. The carbon prism is held by a stout copper plate, and effectually stops sparking with variable loads, while the bulk of the current is collected by the ordinary plate brushes just behind it.

The dynamos working in parallel are used to charge a large set of accumulators. There are 1,800 cells of the Planté type

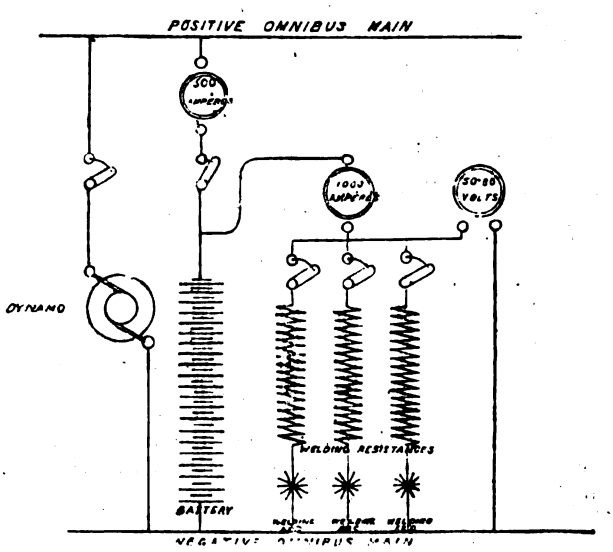

FIG. 3.—Diagram of Connections of Dynamos, Accumulators, Instruments, Resistances, and Arcs.

manufactured by Messrs. Lloyd and Lloyd, under the Benardos patents. The plates, 9in. by 7in., are constructed of zigzag strips of lead burned together by the arc process, and formed in a special manner. The appearance of the cells was very satisfactory; in the two years during which they have been at work, it has not been necessary to replace a single plate. The Planté type is suitable for this work, since very small storage capacity in ampere-hours is needed, the function of the battery being simply that of a fly-wheel. It frequently gives a current twice that of the dynamos, and is capable of yielding a very heavy discharge, which, even though lasting for a very short time, would ruin a pasted plate.

Digitized by Google

In addition to the accumulators, regulating resistances are employed (Fig. 3), both in the instrument room, and beside each bench, every workman having a switch close at hand to enable him to regulate the current to suit the job in hand. In the instrument-room, a number of voltmeters and ammeters show the performance of the dynamos and the current used in the shop. The usual current for each arc is about 150 amperes at 70 volts.

With the exception of the patent pipe-welding machine, to which we shall allude presently, the whole of the electric work was being done with the simple tool illustrated in Fig. 4. This consists of a wooden handle through which a flexible cable is passed, a metal rod with a split clamp for holding a carbon, and an iron shield faced with asbestos to protect the hand. As a rule, the carbon is the negative pole, while the positive lead is clamped to the table or to the work. This allows a longer arc to be formed, since it is a well-known feature of the electric arc that the positive pole volatilises, and in the present case the vapour of the metal greatly assists in maintaining the arc, which may be drawn out to a length of six inches with a flame 1½ in. in diameter. An arc of two to five inches is generally employed, the longer distance giving a more regular heating effect. The workman generally leaves the current on and places the tool on a support or on the bench. To start the arc he touches the metal, generally in a comparatively cool part near the portion being worked, and in a few seconds the metal is raised to working heat. Ordinary welds are made by placing a piece of iron or steel, weighing from one to two ounces, on the work ; the arc is allowed to play

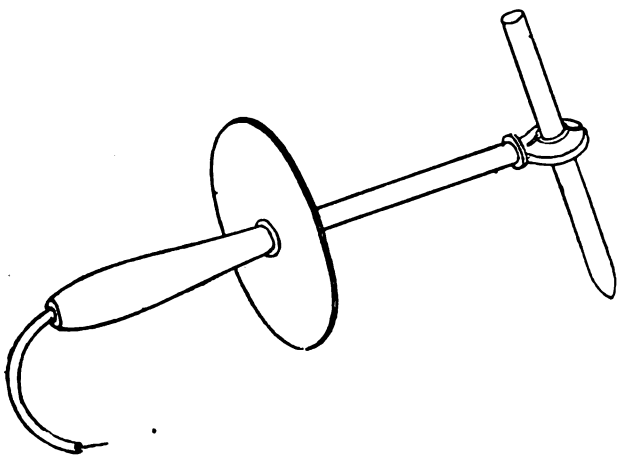

Fig. 4.—Messrs. Lloyd and Lloyd's Patent Carbon Holder.

until the metal begins to run, the degree of heat being carefully adjusted to the particular kind of job ; the arc tool is removed and the portion is hammered in the usual way. Without the hammering, the joint, if made at all, would be very crystalline. It is possible that on the occasion of our visit the men were showing off their skill; but one group of three, engaged on a wedge weld of a large pipe-fitting, while not working harder than ordinary piece-workers, used the arc tool for 12 to 14 seconds, which sufficed to bring the bit of iron and the work on which it was laid to working heat ; 5 to 6 seconds were spent in hammering, and the intervals during which the tools were changed seemed to occupy less than one second. Some 2in. to 2½in. of seam were welded at each heat, and thus about three heats were made in a minute, the work never being removed from the anvil. Hardly any slag or scale was to be seen, the fact that the work was made the positive pole probably created so copious a cloud of iron vapour that the oxygen of the air could not reach the heated surface. For some purposes, such as lead burning, the arrangement is reversed, and the carbon is made the positive pole, the metal in this case probably receives most of the heat by radiation from the carbon. While in the ordinary process of lead-burning great cleanness of surface is essential, with arc-welding the ordinary grey condition of the metal seems to offer but little obstacle.

To heat a considerable surface something more than a long and powerful arc is required. A very interesting pipe-welding machine has been built for making tubes of thin sheets, and in this a mechanical motion of the carbon produces the desired effect. The carbon-holder is illustrated in Fig. 5. A vertical spindle arranged with a feather and depressing lever, exactly like that of a drill, carries a slide at its lower end, and to this, clamped by a bolt, is attached a carbon-holder which can be set with any desired eccentricity. The spindle, which needs but little power to drive it, is mounted on a carriage, and a crank-pin, capable of radial adjustment on a disc, moves the carriage to and fro by means of a connecting rod. Tubes of about 9in. diameter and 2ft. length were being made up from thin sheet. The carbon described a circle of about 2½in. diameter, making 300 to 400 revolutions a minute, while the carriage had a traverse of about 4in., making about 30 strokes a minute. The motion was given by a small motor mounted on the machine, and was controlled by a switch. The tube was placed on a mandril, having a fire-brick lump below the arc. The tube being slipped on, the carbon-holder was brought down to start the arc, and was then raised about three inches and set spinning. The end of the arc was at first confined to one spot on the work, but the metal becoming hot it soon spread out, and after a few seconds described a larger circle than the carbon itself. The rotary motion of the carbon, combined with the traverse, covered some 15 square inches. The current used was from 250 to 300 amperes. An Aron meter registered the whole quantity. Pieces of steel were laid on the seam, and

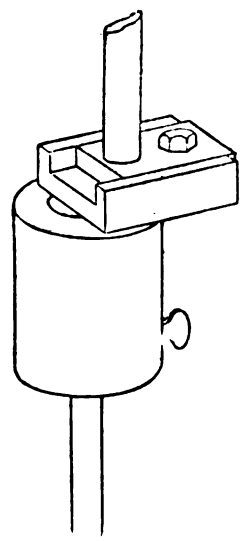

Fig. 5.—Messrs. Lloyd and Lloyd's Patent Mechanical Arc Heater.

when working heat was reached, the arc and the motor associated with it were shut off, the tube shifted longitudinally a foot or so on to the mandril, and a Player hammer rapidly worked up the weld. The hammer was run by another electric motor mounted on the top of the machine, and was controlled by a third switch. These switches were mounted on a sloping metal screen, which protected the smith from the intense heat, but allowed a good view of the work through a red glass pane. The other men were provided with similar glass screens, either fixed to the machine, or held in the hand ; or wore suitable spectacles. Wooden partitions or boxes are arranged round each bench, and a large red glass window is provided in each. A passer-by is thus protected from an accidental glimpse of the powerful arcs. The same men are now engaged in welding who were at work on the process when first started. They are allowed to work in their own way, and are not subjected to constant instructions, as so often happens when a new process is introduced. No difficulty has been found in getting men willing to learn to handle the carbon, and we understand that no welder has ever left the work, or suffered in health or sight.

Hydraulic fittings with complicated branches set at acute angles can be easily made, the seam being welded bit by bit. The sheets from which large and thin elbows and tees are made are cut out into gussets by the use of an arc. The metal drops away like wax, leaving a somewhat ragged cut of about ⅛in. While incomparably superior to chisel and hammer work, and

Digitized by Google

dispensing with heavy punches and shears, the chief advantages in the use of an arc for cutting appear to be that the smith who is to complete the work can cut it out as he pleases, instead of having to use sheets cut out perhaps by another man in another department; and in the facility with which cutting can be done on work *in situ*, where it is not convenient or possible to bring it into the shops.

Associated with the principle of cutting is the important application of the arc to repairing work, an application which, as we have mentioned, received early attention from M. Benardos. Steel and iron castings, facing points, locomotive wheels, pump-rods, and many other objects have been well repaired by this process. The arc is directed on the flaw or crack; the metal runs away; the arc and the piece to be repaired are so handled that a suitable cavity is formed. Sound metal is then filled in by melting down small pieces, which, if necessary, are actually welded into place, a treatment which is, of course, impossible in the otherwise analogous process of "burning on." For steel castings particularly, this process seems to be of great value, since serious flaws are often discovered only after a considerable amount of tooling has been done.

Another distinct branch of th e work is the flanging of tubes. Any thickness of flange can be welded to any thinness of pipe, or the pipe itself can be flanged out. The work is mounted in a lathe, and the arc is directed on to it while it revolves, and when sufficiently hot a presser mounted on a hinged arm completes the weld as it revolves. The job appears to be more easy than the spinning of dishes by a tin-smith.

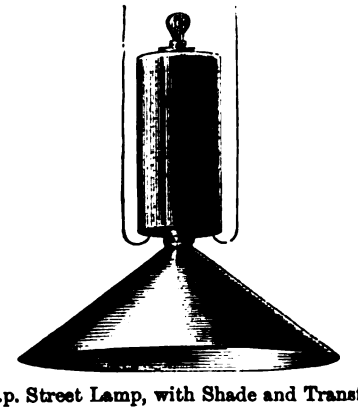
After a thorough experience of gas-welding, Messrs. Lloyd and Lloyd have no hesitation in saying that with two years' experience as sole licensees of electric welding on the Benardos system, the arc-work can be done at one-fourth of the expense of the blow-pipe. This result is largely due to the improved appliances which have been invented by Mr. Henry Howard, of Stonehouse, Kidderminster, the acting partner of the firm at Coombs Wood. Of the quality, it is only sufficient to say that a large quantity of hydraulic fittings are made; and though they do not generally run to more than two inches diameter, they are in all cases tested to high pressures from 1,000lbs. to 3,000lbs. per square inch. Messrs. Kirkaldy's tests of bar welds are highly satisfactory, and the range of possible applications of the process seems to be very wide.

If only because the bulk of the work done by arc-welding, and certainly all those examples which we have mentioned, would not be suitable for the butt welding of the Thomson process, a comparison would be unnecessary. The latter possesses undoubted advantages for welding wire, rods, and bars. It has induced some manufacturers to change their designs in order that its full advantage might be gained. What it could not do can be done by arc-welding, and there are but few jobs which can be done by neither. A most important consideration is the small cost of plant for the arc system. The dynamos are not expected to give the full working current, and their load factor is high. The batteries are not expected to have any considerable storage capacity. The leads are moderate in size. The volts are practically constant, and lights may be run off the same circuit. The ordinary mode of applying the heat is the simple handling of a tool worth a shilling or two. To educate men to use a blowpipe was not difficult, and the change from the blowpipe to the arc is hardly any change at all.

On Monday last a large party of engineers and representatives of the Press left the fogs of London by a special train, and after having luncheon at Birmingham, where the sun was shining brightly, visited the Coombs Wood Tube Works. In the handsome mess-room was a display of samples of work done, including very large bends and other fittings, flangings, repaired forgings and castings, and Kirkaldy test pieces. The works were then visited, and the processes of electric welding and other work were watched with great interest, a large pile of dark red glass screens having been provided for the visitors; more than one of whom, however, suffered afterwards from accidental glances at the arcs or careless use of the screens. The extensive gas-tube department, stores, and fitting-making shops were inspected, and all questions were answered and information was freely given to inquirers by the members and the staff of the firm.

A TWO-THOUSAND VOLT STREET LAMP.

Street lighting by alternate current has for some time past presented considerable difficulties. In most cases transformers are arranged in the houses, and the stations have high-pressure leads only. To run incandescent lamps it is, therefore, necessary to employ transformers and a system of low-pressure



A 32-c.p. Street Lamp, with Shade and Transformer.

leads. Messrs. Swinburne and Co. have brought out a lamp which contains a small transformer, and is connected direct to the high-pressure system without any low-pressure leads. A 32 c p. lamp with protector is arranged under a large enamelled iron shade, which is secured to the base case of a small transformer.

A NEW FORM OF ELECTRIC MEASURING INSTRUMENT.

The accompanying illustration shows an electrostatic instrument recently brought out by Messrs. Swinburne and Co. for experimental work in connection with alternate currents. Instead of quadrants there are two pairs of half discs, so that the angle of deflection can be large. The needle consists of two half discs fastened on a metallic arbor. It is held by top and bottom suspensions. One disc is in the upper box and the other in the lower. The boxes are connected, not to ordinary terminals, but to highly insulated flexibles, as the ordinary

An Electrostatic Volt- and Watt-meter.

terminals are not suitable for high pressures. This instrument can be used as a voltmeter, or it may be connected up to measure power by any of the various methods involving two readings. It can also be connected up as a direct-reading wattmeter. The electro-magnet below the boxes acts on a copper drum, and renders the instrument dead beat. This magnet is excited by a cell. For large readings the torsion head and pointer on the top of the instrument are used; but for small readings the mirror is employed. Four of these instruments have been lent to Dr. Fleming to carry out experiments on the measurement of power by various different methods.

PHYSICAL SOCIETY.

At the meeting of the Physical Society on the 18th inst., a "Note on Interference with Alternating Currents" was communicated by Mr. M. H. Kilgour. Whilst studying Dr. Fleming's Paper on "Some Effects of Alternate Current Flow in Circuits having Capacity and Self-Induction," the author constructed some additional curves. He was thereby led to investigate whether the serious rises of pressure produced by adding capacity would occur over considerable ranges of capacity, or whether they would only take place when the capacity was nearly equal to a particular value. Taking the case of a condenser of capacity C farads, in series with a circuit of resistance R ohms, and inductance L henrys, he showed that the maximum value of λ (the ratio of the pressure across the condenser terminals to that across the condenser and inductive resistance) is obtained when

$$C = \frac{L}{R^2 + p^2 L^2} \quad \ldots\ldots\ldots \quad (1)$$

where $p = 2\pi$ times the frequency. The maximum of λ being given by the expression

$$\Lambda = \frac{\sqrt{R^2 + p^2 L^2}}{R} \quad \ldots\ldots, \quad (2).$$

If we take the values R=10, and $p = 2\pi$ 1,000 curves plotted from equations (1) and (2) between C and L, and between Λ and L had been drawn. The C L curve rises to a very sharp peak at L=·0015 and falls rapidly. That between Λ and L starts horizontally and bends upwards, and approximates to an inclined straight line values of L greater than 0·002; when L=0·1, Λ=63. Considering the question of the range of capacity with which a given rise of pressure can occur, it was pointed out that when the values of L, R, and p are such as to make a large rise possible, a rise exceeding a moderate value can only be obtained for values of C differing little from that given by equation (1). On the other hand, when the circuit is such that the maximum rise possible is not large, then a rise exceeding a given moderate value can be obtained over a much wider range of capacity. Hence the author concludes that the larger the possible rise, the smaller is the probability of a serious rise occurring. The effect of shunting the condenser by a circuit of resistance r and inductance l is next dealt with in the Paper, and the values of C which make Λ a maximum determined, as well as the maximum value Λ can have. Subsequently the author examines whether the practical case of an alternator feeding a transformer through a concentric cable may be simplified without introducing serious error by assuming the capacity concentrated at either end of the cable, and concludes that in ordinary cases little error will be thus made. In an experiment made with a 100-kilowatt alternator, $\frac{3}{4}$ mile of 37/15 concentric cable, and an 18-kilowatt transformer, a rise of $\frac{1}{4}$ per cent. was found to occur at the terminals of the alternator when the cable was connected. Putting on the transformer, unloaded or loaded, produced little change in the rise of pressure; this in all cases being between 0·2 and 0·3 per cent.

DISCUSSION.

Dr. SUMPNER asked whether the conclusions as to the range of capacity with which a given rise of pressure was possible was true for small rises such as occur in practice. Cases where the maximum possible rise was of the order 63 were not likely to occur at ordinary frequencies. The highest rise he had ever known was 11. He thought the times constant of the inductive coil chosen, viz., one-hundredth of a second, was very large. In circuits containing iron it was practically impossible to get such large time constants, for the power spent in the iron increased the effective resistance. Referring to the narrow range of capacity within which large rises were possible, he pointed out that such cases were found in Hertz's resonators where the rises were immense, but to obtain them the adjustments had to be very accurately made.

Dr. S. P. THOMPSON said he regretted that Prof. Fleming was not present, for he had recently investigated Hertz's experiments, and had obtained curves very similar to those got for the Deptford main. The curve between Λ and L was very interesting. It was, in fact, a curve between the secant of the angle of lag and L, as could be seen from formula (2). In practice, one would be working on the lower portion, and hence the rises would be small.

Mr. KILGOUR explained that in the Paper his first object was to show that the product of the range of capacity between which a rise greater than a given value would occur and the maximum possible rise was approximately constant for different circuits. Secondly, he wished to prove that the capacity of concentric cables could be assumed to be localised at either end without introducing much error in the rises of pressure calculated therefrom.

Dr. THOMPSON, speaking of nomenclature, regretted that the word "inductance" should be used sometimes for L and at other times for Lp, and thought its meaning should be restricted to the latter.

Prof. PERRY said a name was needed for "coefficient of self-induction." "Resistance" was practically independent of frequency, and "inductance" should have no reference to frequency.

Dr. SUMPNER thought it important to have a name for Lp, for that quantity came into calculation most frequently. He would have preferred that "inductance" should mean Lp; but Mr. O. Heaviside, who introduced the term, had used it for L.

The PRESIDENT remarked that some time ago Dr. Sumpner and himself felt the need of a name for Lp, and thought of using "inductance"; but on referring to Mr. Heaviside's articles found it used for L.

Dr. C. V. BURTON asked whether the word "self-induction" could not be used as an abbreviation for "coefficient of self-induction."

Dr. THOMPSON pointed out that this word already had a meaning, viz., L multiplied by current.

Dr. BURTON then suggested that "inductivity" might be applicable.

Dr. THOMPSON said the word "impedance" was also used ambiguously; for the sense in which Dr. Lodge used it in his "Modern Views of Electricity" was not the same as the vector sum of R and Lp.

Prof. PERRY recalled the fact that "impedance" had been defined by the Committee of the British Association as the ratio $\frac{\text{effective voltage}}{\text{effective current}}$.

Dr. THOMPSON said this definition was only applicable to periodic currents, and not to intermittent or transient ones.

The PRESIDENT said he understood the first object of Mr. Kilgour's Paper was to inquire whether the dread of rise of voltage occurring when concentric mains were used need exist. When Dr. Fleming's Paper was read the general idea was that concentric cables were dangerous. In the discussion on it he, amongst others, had pointed out that the chance of a large rise of pressure was not a serious one. Mr. Kilgour had now shown that the range of capacity over which a particular rise could occur is inversely proportional to the maximum rise possible in the particular circuit. When the circuit was such that a large rise was possible, the probability of any serious rise taking place was very small, hence the fears of large rises were more or less unfounded. The second part of the Paper was to show that ordinary problems on concentric cables could, in practice, be treated with sufficient accuracy by assuming the capacity localised at either end of the cable, instead of distributed along its length.

THE THEORY OF THE RUHMKORFF COIL.*

BY M. COLLEY.

The Ruhmkorff coil has been the object of numerous researches bearing almost entirely upon the phenomenon of luminous discharge; but the author has studied from an experimental and theoretical point of view the electric phenomena which are produced on opening the primary circuit. The ends of the primary were joined to the plates of a condenser with a maximum capacity of 5·3 microfarads, and the circuit could comprise at will several supplementary coils of low resistance and high self-induction. The coil had no iron core. The image of the spark was thrown on to a revolving mirror. An ordinary Geissler tube was employed, and it was covered with black paper, except along a narrow longitudinal strip, which was only broken at the conical portions comprised between the broad and narrow parts of the tube. The tube was placed vertically before the mirror, which revolved round a vertical axis. The primary current was interrupted at the moment when the mirror was turned towards the observer. The condenser of the apparatus was replaced by one formed of 300 sheets of tinfoil, separated by paraffined paper. The self-induction of the external coils was considerably greater than that of the primary coil alone, their presence had the effect of retarding and regulating the discharge.

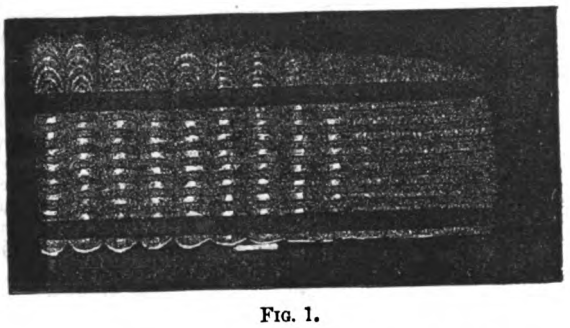

FIG. 1.

When the secondary circuit was open, the spark gap being from 30 to 40cms., the discharge shown in Fig. 1 was obtained, a large inductive coil and all the available capacity being placed in the primary circuit. A series of equidistant vertical bands, separated by less brilliant ones, are to be seen ; the difference of appearance becomes gradually less pronounced ; and everything melts into a train of light, the brightness of which is steadily diminishes. The horizontal bands correspond to the striæ visible in the narrow part of the tube ; the movement of the striæ gives them this wave-like appearance. The black bands are caused by the break in the slit cut in the black paper cover. At the lower end (+electrode) a curious appearance, indicating the presence of layers in rapid motion, is noticeable, the colour is pale blue, and the phenomenon allows one to see for certain at any moment the direction of the discharge.

A study of Fig. 1 will show us that we have to do with two superimposed currents, one dead-beat, the other periodic ; it is the latter which causes the horizontal band. The train of light indicates that the first discharge lasts after the periodic one has become sensibly equal to zero. Finally, as the fringes have no dark portions, it follows that the total discharge is never annulled, or, more exactly, does not fall to the minimum value below which a discharge ceases to take place.

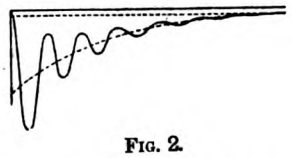

FIG. 2.

In Fig. 2 are shown the variations of the discharge. The dotted curve is the dead-beat portion, the full curve the periodic portion ; the dotted straight line shows the minimum value necessary to ensure a discharge.

If we employ a smaller coil with a 2cm. spark gap, somewhat different phenomena are observed, which may be interpreted as follows :—The dead-beat current, which depends solely upon the nature of the secondary circuit, diminishes more rapidly, whilst the periodic current, which depends only on the primary circuit, remains much the same. The periodic portion is, therefore, predominant.

When the secondary circuit is open we can investigate at the same time the strength of the discharge and the difference of potential. Two batteries of about equal capacity, each composed of four Leyden jars, had their external coatings connected to the terminals of the induction apparatus. Their internal coatings were joined together through the Geissler tube. The discharge which passes through this tube may be considered as having at every instant the same value as that which traverses the secondary coil. It was possible by means of a well-insulated commutator to cut out all but one of the Leyden jars in each battery, and the primary external inductive coils were replaced by zigzag resistances. With the large Ruhmkorff coil the discharges shown in Figs. 3, 4, and 5 were obtained.

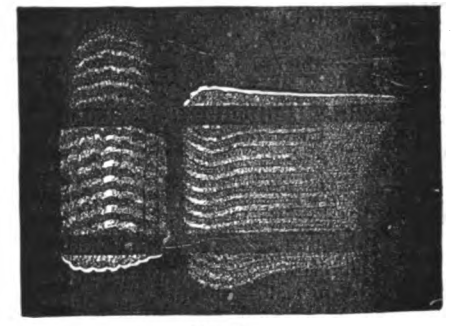

FIG. 3.

FIG. 4.

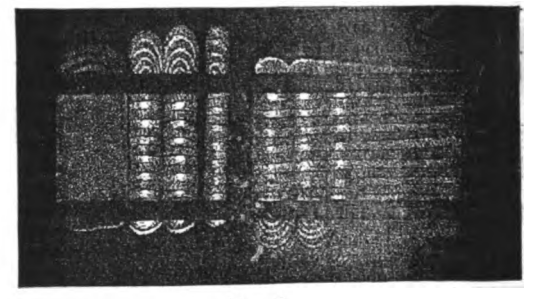

FIG. 5.

In the case of Fig. 3 the primary circuit did not contain any external inductive coil, but only a zigzag resistance of 2 ohms. The discharge attains a maximum, changes sign, and then tends to zero.

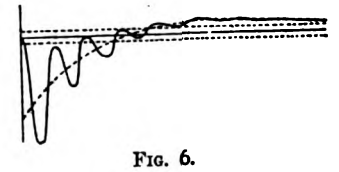

FIG. 6.

In Fig. 5 the self-induction of the primary was increased. The rose-coloured undecided streak on the left was due to a too slow rupture of the primary current (the spark was very powerful). Fig. 6, which shows some curves derived from an equation given by the author, explains all the results.

In the previous cases we were close to the limit where the dead-beat factor becomes periodic. If we suppress three Leyden jars we obtain the discharge shown in Fig. 4 ; the fringes are about twice as broad as in the previous case, which was to be expected, since the capacity was only one-fourth.

Other phenomena were observed, of which the theory remains to be deduced. With four Leyden jars we can, by breaking the primary current, more smartly obtain oscillations in the secondary. The same result is obtained without a commutator by using more

* *Journal de la Société Physico-Chimique Russe. Wiedemann's Annalen*, 1891. Abstract of a translation in *La Lumière Électrique*, November 14, 1891.

Digitized by Google

Leyden jars. When low capacities are employed, isolated luminous bands separated by dark intervals are obtained, and the discharge only retains for a very brief period sufficient strength to traverse the tube. With a small coil the results are much the same, the secondary discharge is weaker, and the influence of the primary is greater.

In conclusion the author asserts that his experiments completely verify his theoretical results; the movement of electricity in the secondary is, therefore, well represented by the formula obtained by him. Moreover, and this point is very important, the phenomena which are produced in ordinary apparatus differ in no way from those investigated by the author. For example, the suppression of the external coils in the primary only has the effect of accelerating the discharges and of rendering them less regular. The capacity of the coils themselves replaces that of the Leyden jars employed in the experiments, and allows us to obtain oscillatory discharges even with small apparatus, in which the ends of the secondary are insulated.

It is no use to think of employing an electrometer in the direct investigation of such rapid variations of potential; but the author has discovered the following phenomenon, and on investigation it may be found applicable. If we light a gas flame at the end of a slightly contracted glass tube and introduce a metallic wire into the tube, the flame jumps up sharply every time the wire is charged. If we connect the wire to one pole of a Ruhmkorff coil, the other pole being to earth, we see in the mirror an oscillation of the flame, but it is so fantastical and irregular that the author has up to the present found it impossible to make anything out of the phenomenon.

LEGAL INTELLIGENCE.

Savory and Moore v. London Electric Supply Corporation.

In the Chancery Division of the High Court of Justice, on Friday, Mr. Justice Kekewich gave judgment in the case of Savory and Moore *v.* London Electric Corporation, which was an action to restrain the defendants, who occupy buildings adjacent to the plaintiffs, from using their buildings as a station for converting the electric currents generated by them at extra high pressure, or as a station for the distribution of electric currents at extra high pressure, and from storing or using transformers and electric cables at the said premises, and from using or allowing to be used the said premises as a converting or distributing station in connection with their supply of electricity.

Mr. Warmington, Q.C., and Mr. Vernon Smith appeared for the plaintiffs; and Mr. Moulton, Q.C., and Mr. W. F. Hamilton for the defendants.

His LORDSHIP, in delivering judgment, said that there was now no imminent danger against which the plaintiffs were entitled to protection was clear beyond dispute; but that there would be no such danger in the future was not equally clear, because defendants' plans above the basement were wanting in precision, and a disposition to be guided by circumstances and the exigencies of trade formed an awkward factor in the sum of possible results, into which, of course, inexperience and carelessness largely entered. The powers and, therefore, the dangers of electricity could not be regarded as known even by scientific men with sufficient accuracy to justify a positive statement respecting possible results in hypothetical circumstances, especially when the locality was in the heart of a crowded city. He had thought that the parties might have come to an arrangement; but the plaintiffs required, as they were entitled to do, a decision on the merits; and, therefore, he must have regard not to the present but to the past. To the claim of the plaintiffs the defence was merely that the action was premature. The defendants said that if the plaintiffs had waited a little while and had given only a slight consideration to their reasonable assurances, they would have been satisfied; that what had happened before would not and could not recur, and that any shortcomings of the past would be avoided in the future. The evidence conclusively proved that the operations of the defendants as conducted prior to November 15, 1890, were of imminent danger to the plaintiffs, and this was due to two causes, singly or in combination—first, the inherent, though latent, danger of the works; and secondly, the neglect of precautions. It followed that any injury to the premises would have been actionable, and seeing that the injury, if it happened at all, was likely enough to be serious, alarm was natural and justifiable. That it was still natural after the defendants' premises had been gutted on November 15, 1890, was sufficiently clear; but was it justifiable? If it was justifiable before plaintiffs communicated with the defendants, did it remain so after that time? To answer that question it was necessary to examine the facts. Within a short period there had occurred on the defendants' premises two fires traceable to the causes he had mentioned. One of the fires was soon extinguished, and, so far as the plaintiffs were concerned, it did no harm. The other, which occurred on November, 15, 1890, was of a more serious character, more alarming, and more destructive. It destroyed the defendants' building, and the injury extended to the plaintiffs' premises. Who could blame the plaintiffs for thinking that this incident was likely to be repeated with disastrous consequences, and that it behoved them to take measures for the protection of their property? Giving them credit for such an acquaintance with the defendants' operations and their conduct of business as might reasonably be presumed, they would expect that, with as little delay as circumstances permitted, the defendants would again make the building available for supplying their customers, and that the conditions of the restored building would not substantially differ from those just destroyed. The experienced past and the anticipated future therefore combined to make the plaintiffs apprehend danger, and to urge them to take active measures to prevent a repetition of such danger. This they did promptly and prudently. They issued a writ and communicated with the defendants' solicitors in a temperate letter deserving of commendation. In that letter they asked for an undertaking in the terms of the injunction which they claimed by their writ. He held that the plaintiffs were right in asking for such an undertaking. It did not appear that the elements of danger from fire had been or would be completely removed, and therefore he granted the plaintiffs an injunction in the terms in which they had said they were willing to accept an undertaking, with costs.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *December* 11, 1891.

The Eickemeyer Motor.—Another gearless motor has recently attracted attention in electrical circles. This is the Eickemeyer machine, which was really the first of the gearless type; but it has kept very much in the background until within the past few weeks. Mr. Eickemeyer's plan is to use a single large motor, supported on a truck instead of on an axle, and driving both axles by means of a crank shaft and connecting rods. In addition, the wheels on the car are of considerably smaller size than usual, so that the requisite car speed can be obtained without too great a reduction of armature speed. The purpose of this peculiar arrangement is by cushioning the weight of the motor to prevent damage to the armature from shocks. Mr. Eickemeyer is especially fearful of the danger of injuring the armature when it is placed directly on the car axle. The thing to be criticised in this device is the severe strain imposed on the crank shaft by this very vibration. Several Eickemeyer cars are in operation in Lynchburgh, Va., and run with a considerable degree of success, although private reports from that point indicate that there have been many repairs. The Western Electric Company, of Chicago, is manufacturing a number of these machines, and they will shortly be at work on a more extensive scale.

Storage Battery Traction.—Another storage battery traction scheme is afoot; this time it has taken the form of a company, with Mr. Conrad L. Jordan, a gentleman well-known in financial circles, at its head, and with $500,000 capital, to exploit the McDougall system. Mr. McDougall is one of the early workers in the electrical railway operations of the Edison Company; and, so far as can be ascertained, has a very good form of motor truck. The batteries, however, are the indeterminate feature of this scheme. Up to the present he has been using a large variety of cells with tolerable results, but there is nothing sufficiently radical in it all to warrant any great amount of faith in the undertaking.

Electrical Litigation.—In legal circles things of electrical interest are, first, the trial on appeal of the incandescent lamp case, which will probably take place the first of the year; and, second, the "feeder" and "main" suits, two in number, instituted by the Edison Company to substantiate their patent rights to the feeder system. These have been very sharply called in question, and the coming trials will be of considerable interest and importance. The result of the incandescent lamp decision has not as yet been the suppression of the smaller manufacturers or any compromise, and the opinion is freely expressed that it will be a long time before the Edison Company is able to collect any damages from alleged infringers. The storage battery decisions of last year and this year do not seem to have led to any special results as yet. The Julian Company, in spite of the fact that it has an exclusive licence under the broad Brush patent, has been for a couple of years embarrassed in its manufacture by the Faure patent, in the hands of the Accumulator Company. So that just now both are still doing business, neither of them to any considerable extent, despite the fact that both have put on the market accumulators which compare very favourably with the best of those made abroad.

Polyphasal Generators.—At the next meeting of the American Institute of Electrical Engineers a Paper on polyphasal

Digitized by Google

generators, by Dr. M. I. Pupin, is promised. As this is the first discussion of this subject before the Institute, it will probably attract a great deal of attention, and the mathematical contingent will be out in full force.

The Proposed International Electrical Congress at Chicago.—The proposed International Electrical Congress for the World's Fair in 1893 seems to have stirred up a considerable amount of ill-feeling in Western electrical circles. In spite of the fact that this Congress was originally proposed and endorsed by the American Institute of Electrical Engineers, that body (the only electrical organisation in the country possessing scientific standing) has been completely ignored in the matter, Prof. Gray having, through local influence brought to bear on the Government, been appointed to take charge of the matter in connection with divers other Chicago electricians. Prof. Gray is not a member of the American Institute of Electrical Engineers, and, apparently, local pressure has been brought to bear on him to stir up dissatisfaction, and to strain the relations between the Exposition authorities and the Institute. Considerable indignation has been expressed by the members of the Institute at the high-handed indifference with which they have been treated up to the present, and steps have been taken towards a proper adjustment of the difficulties. If an attempt is made to hold an Electrical Congress without the co-operation of the Institute, to gratify any personal prejudices on the part of outsiders, the result is not likely to be a shining success.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Offices not later than first post Thursday morning.*]

NOW READY.—"THE ELECTRICIAN" PRIMERS (38 in all. Vol. I., 20; Vol. II., 18), in two volumes. Price per volume 2s. paper covers, 2s. 6d. cloth; post free, 2s. 2d. and 2s. 9d. respectively. Single copies, 3d.; post free, 3½d. Prospectus on application to the Publisher.

THE ELECTRIC LIGHT AT SPRING GARDENS.—The tender of Messrs. J. D. F. Andrews and Co. (*see* last week's *Electrician*) has been recommended for acceptance.

MESSRS. THOS. FLEMING, SON, AND CO.—This firm have just executed an order for three 10in. double leather belts for the Gülcher Company, which are to drive their new electric light installation at the Crystal Palace. Messrs. Fleming inform us that they have at the present time belts running at the Crystal Palace which were supplied in 1881 for driving all the dynamos there, and these belts have worked continuously during the 10 years without hitch or accident.

ENGLEBERT AND CO.—We have been favoured with a copy of a very useful Calendar, published by this firm, and Messrs. Englebert and Co. courteously invite applications for further copies from users of their specialities.

THE PRICE OF GAS.—The Gas Light and Coke Company have selected the present festive season for a notification to the effect that the price of common gas of 16-candle illuminating power will be 3s. 1d. per thousand cubic feet, an increase of fourpence per thousand.

THE NATIONAL TELEGRAPH WORKS.—We have received a copy of the revised and reduced price list of the Leclanché batteries manufactured by this firm.

BULLER, JOBSON AND CO. (LIMITED).—A meeting of the shareholders of this Company (in voluntary liquidation—now Bullers Limited) will be held at 4, Waterloo-street, Birmingham, on January 14, 1892, at 3 p.m., to receive an account of the winding-up.

HUMBOLDT ELECTRIC POWER AND MINING COMPANY (LIMITED).—A meeting of the shareholders of this Company (in voluntary liquidation) will be held at the Great Eastern Hotel, Liverpool-street, E.C., on January 13, 1892, at 12, to receive the liquidator's report.

SHEFFIELD TELEPHONE EXCHANGE AND ELECTRIC LIGHT COMPANY (LIMITED).—A meeting of the shareholders of this Company (in voluntary liquidation—reconstructed under the same title) will be held at the registered offices, Commercial-street, Sheffield, on January 14, 1892, at 3 p.m., to receive an account of the winding-up.

MACHINERY AND HARDWARE COMPANY (LIMITED).—We have received a copy of the annual export catalogue of this Company, which is, as usual, full of illustrations, particulars, and prices relating to machinery and hardwares of many of the leading makers in Great Britain. This is the sixth annual edition of the catalogue, and is published in the English and Italian languages. Over 500 specialities are referred to.

MUNRO'S ELECTRICAL MANUFACTURING COMPANY (LIMITED).—We are informed that this Company have, in response to requests from their London customers, taken show rooms at 17, Princes-street, Hanover-square, W., where Mr. H. W. Hooper will represent them. The stock on show will include samples of hand-hammered and wrought arc work in electroliers, pendants, brackets, &c.

ELECTRIC APPARATUS COMPANY (LIMITED) (IN LIQUIDATION).—Mr. John Hannan (of Messrs. Broads, Patterson, and Company-1, Walbrook, E.C.), liquidator in this estate, issues a notifica, tion, dated December 17th, that a first and final dividend of 1s. 6d. in the £ has been declared, and is payable to the creditors of this Company at his offices on and after Monday, the 21st inst. (except Saturdays), between 11 and 4.

DOMESTIC TELEPHONY.—With the cheapening of telephonic apparatus consequent upon the expiry of master patents, the use of the telephone as a means of internal communication in large warehouses, hotels, &c., is likely to become fairly general. For this purpose the Ader magnetic telephone, acting both as a receiver and transmitter, is very suitable. We have before us an illustrated price list of Ader apparatus for domestic and short-line purposes, issued by Mr. G. A. Nussbaum, of 29, Ludgate-hill, London, Agent of the Société Générale des Téléphones. Ader telephones have already met with considerable vogue in this country, and from what we have heard, appear to give universal satisfaction, and providing they can compete in point of view of price and certainty with speaking tubes and rival telephonic apparatus, there should be a good demand for them. The recent installation by Mr. Langdon, Superintendent of the Midland Railway, throughout the reconstructed Adelphi Hotel at Liverpool, referred to in our "Notes" last week, and the instruments for which were supplied by Mr. Nussbaum, is described to us as a great success.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

November 23, 1891.

20,293. A. C. SNELL. Cornwall. Improvements in accumulators used for marine purposes and the like.
20,314. J. GRATTON. Nottingham. Electrical thermometer.
20,322. H. W. MILLER. London. An improved means of reproducing the indications of electrical measuring instruments at a distance.
20,328. R. KENNEDY. Glasgow. Improvements in producing alternating currents differing in phase.
20,356. W. STORR. London. Improvements connected with electric arc lamps.

November 24, 1891.

20,367. A. SHIELS. Glasgow. Improvements in couplings for electric wires.
20,389. E. T. WHITELOW. Manchester. Magnetic microphone.
20,407. R. PAPE. Liverpool. Improvements in the manufacture of a hard insulating material.
20,413. G. BAMBERG. London. Improved electrolytic apparatus, more particularly applicable for manufacturing caustic soda and other products from salt, but also applicable to other purposes.

November 25, 1891.

20,485. F. BRYAN. London. Improvements in automatic safety devices for electric circuits.
20,492. L. B. MILLER and M. W. WOODS. London. Regulating electric currents.
20,496. A. CHAMPION and J. MOSS. London. Electrical switch.
20,506. SIR C. S. FORBES. London. Improvements in microphone transmitters.
20,508. T. H. WILLIAMS. London. Improvements in and relating to dynamo electric machines.
20,524. W. W. HORN. London. An improved combined fitting for gas and electric lights. (O. Strom, United States.)
20,527. J. O. FOWLER, JUNIOR. London. Improvement in hollow cast joints for metal-armoured conductors.
20,530. A. B. W. H. COMBS. London. Improvements in and relating to ships' telegraphs.

November 26, 1891.

20,542. T. J. RICKARD. Newport. Improved incandescent lamp-holder and form or shape of incandescent lamps.

Digitized by Google

20,545. A. R. Bennett and R. McLean. London. An improved system of telephonic exchange signalling.
20,595. F. R. Boardman. London. Improvements in arc lamps.

November 27, 1891.

20,623. W. Maxwell. London. Improvements in telephone transmitters.
20,629. C. M. Dorman and R. A. Smith. Improvements in holders for incandescent electric lamps.
20,642. E. Burgess. London. Improvements in apparatus for automatically controlling the direction of electric currents singly or in groups as for illuminating advertisements and the like.
20,678. F. Pohl, Junior. London. Improvements in electric burglar alarms.
20,689. M. Mackay. London. Improved cementitious and electric insulating compounds.
20,699. A. W. Thatcher and A. Devereux. London. A new or improved electric indicator.

November 28, 1891.

20,718. P. Pickney. Southsea. Magnetic electric boot and shoe (iron and steel) grindery.
20,748. F. Scudder. London. Treatment of and production of valuable products from sludge obtained by electrical treatment of sewage.
20,799. W. H. Blakeney. London. Improvements relating to electric call systems and apparatus for use therein.

November 30, 1891.

20,814. J. M. Richards and J. Stephen. London. Simultaneous telegraphy and telephony.
20,825. H. Edmunds and G. E. Preece. London. Improvements in the insulation or covering of or for electrical cables.
20,827. D. J. Quinn and P. W. Hoffmann. London. Improvements in electric lighting attachments for gas burners.
20,830. E. Böhm and E. Bailey. London. Improvements in electric safety lamps for mining and other purposes.
20,837. C. H. Woolf, A. E. Hayman, and A. D. R. Jameson. London. Extracting gold and silver from sea water by electrolysis.
20,840. J. Nebel. London. Improvements in armatures of dynamo-electric machines.
20,864. T. C. Hodgkinson and H. T. Tompsitt. London. A new and improved combined electro-medical apparatus coil and battery.
20,865. A. J. Eli. London. An improved electric railway system. (J. S. Gerbe, United States.)

December 1, 1891.

20,886. W. C. Martin and J. Hunter. Glasgow. Improvements in or connected with electric masthead and side lights for ships.
20,900. W. Macpherson. London. Improvements in arc electric lamps.
20,913. M. W. Dewey. London. Improvements in electrically-propelled vehicles.
20,922. C. Lütcke. Liverpool. Improvements in storage batteries or accumulators.
20,924. M. W. Dewey. London. Improvements in and relating to electric fire engines.
20,930. M. W. Dewey. London. Improvements in electrically-propelled vehicles.
20,933. M. W. Dewey. London. Improvements in and relating to electrically-propelled hose carts or carriages.
20,936. M. W. Dewey. London. Improvements in electric-heating apparatus.
20,969. T. J. Holland. London. Improvements in electrolytic tanks.
20,970. J. W. T. Cadett. London. Improvements in apparatus for measuring and registering electric currents.
20,972. G. J. May. London. Improvements in combined haulage and electric cables.

December 2, 1891.

21,018. F. T. Schmidt. Bradford. Improvements in the construction of electrically controlled arc lamps.
21,028. W. Walton and E. Lester. London. An improved gas or electric light appliance attached to a stud for the purpose of illuminating a dress shirt front.
21,033. L. Pyke and E. S. Harris. London. Improvements in dynamo machines.
21,034. P. E. Singer. London. Improvements in musical instruments operated by electricity.

December 4, 1891.

21,142. W. P. Adams. Barnes. Improvements in ceiling roses for electrical fittings.
21,143. W. P. Adams. Barnes. Improvements in electrical cut-outs.
21,154. C. S. Snell and Woodhouse and Rawson United (Limited). London. Improvements relating to electrical lamp holders.
21,173. R. H. Courtenay. Wandsworth-road. Means and electrica apparatus for promoting the growth of bulbs and other plants.
21,187. P. V. M'Mahon. London. Improvements in regulating steam engines working dynamo electric machines and apparatus for that purpose.
21,207. T. Sturgeon. London. An improved electro-motor.
21,211. W. H. Blakeney. London. An improved electric-call system and apparatus for use in connection therewith.
21,214. A. J. Boult. London. Improvements in meters or recorders of electricity. (C. Lebois).

December 5, 1891.

21,245. J. L. Clerc, J. Picard, and J. Rougeant. London. Certain improvements in electric alarm and call clocks.
21,246. J. M. M. Munro. Glasgow. Improvements in compound winding of groups of dynamos.
21,265. H. H. Brown, A. Elliot, and Chetham-Strode (Limited). London. A new or improved coin-freed device for operating electric circuits.

December 7, 1891.

21,344. J. E. Spagnoletti. London. Improvements in dynamo-electric machine commutator brushes.
21,354. H. Aron. Liverpool. Improvements in apparatus for measuring electric currents.
21,363. J. Peral. London. An improved electric lift.
21,369. H. H. Lake. London. Improvements in switches for primary or secondary batteries. (H. Müller, Germany.)
21,379. A. Bernstein. London. Improvements in dynamo-electric machines.

December 8, 1891.

21,442. H. H. Lake. London. Improvements in secondary or storage batteries. (J. L. Roberts, United States.)
21,448. S. Pitt. London. Improvements in the manufacture of filaments for incandescent lamps. (L. K. Böhm, United States.)
21,449. F. G. Howard. London. Improvements in switches for electrical purposes.
21,476. A. G. Waterhouse. London. Improvements in electric meters.

December 9, 1891.

21,505. R. Kennedy. Glasgow. Improvements in methods for producing multiphase alternating currents and in apparatus therefor.
21,541. L. Pyke and E. S. Harris. London. An improved method of mechanically strengthening dynamo electric machine inductors.
21,551. S. Pitt. London. Improvements in apparatus for the projection of electric light. (S. Harlé and Co., France.)

December 10, 1891.

21,571. J. Stevenson. London. Improvements in an apparatus for showing the principle of the utilisation of heat as a source of electricity. (V. Harbec, France.)
21,651. W. H. Dingle and J. M. Urquhart. London. A new or improved method of making and breaking electric circuits, and of apparatus therefor.
21,668. A. Marr. Manchester. Improvements in electric switches.
21,690. E. Böhm and E. Bailey. London. An improved safety switch.
21,691. E. Böhm and E. Bailey, London. A variable resistance switch.
21,702. W. P. Thomson. Liverpool. Improvements in and relating to the construction of electrodes of large dimensions for accumulators, and to supporting the same in their cells. (A. V. Kerckhove, Belgium.)
21,720. J. C. Howell and P. E. Pownall. London. Improvements in switches for regulating currents of electricity.
21,723. W. Routledge. London. Improved means of and appliances connected with electrically regulating the feed of carbon to arc lamps.

COMPANIES' MEETINGS & REPORTS.

The Electric Construction Corporation (Limited).

The third general meeting of this Corporation was held on Tuesday at the Cannon-street Hotel, under the presidency of Mr. J. Spencer Balfour, M.P.

The SECRETARY (Mr. W. Samson) read the notice calling the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN referred with regret to the absence, through illness, of the Company's Chairman, Sir Henry C. Mance, and said that, dealing with the profit and loss account, by sales and work during the year ended September 30, 1891, the total receipts amounted to £160,000 odd, and as during the whole of the year their works had been busy, this meant over £3,000 per week of work of a manufacturing character alone. The cash and shares for licences granted, patents sold, and profits upon formation of subsidiary companies, amounted to £64,710. He wished to point out that this represented nearly all profit, and was therefore a most gratifying feature. The patents which had been sold were not, so he was informed, included in the original sales from Elwell Parker to this Corporation, and had been developments of patents which had then been floating through the mind of their extremely able engineer, Mr. Thomas Parker. Those patents had been sold or licences granted to use them, and had not in any way diminished the security they acquired when they purchased their works. These were additional profits and security acquired since that time, thanks to the genius of Mr. Parker. Out of the £64,000 they had written off no less an amount than £20,000 in diminution of capital. He thought this was an exceedingly prudent policy, and if it was persevered in for a few years to come, and their patents still remained as valuable, the result would be that their capital charges would thereby be very materially reduced, thus adding to their capacity to pay dividends. This year they proposed to write off £20,000, or, roundly, a third of the total amount received from these patents. After meeting all charges there remained a profit of £44,710. Coming to profit and loss account they would see that they had debited themselves with £3,099 for depreciation of machinery, and they had endeavoured to keep their machinery up to the highest point of efficiency. In that way they had expended over £3,000, and at the same time they had deducted £10,000 of their profit to meet depreciation of machinery; so that, as prudent men, it would be seen, that they had adopted a double course—they had put aside £10,000 to meet depreciation, and they had spent £3,000 in preventing that depreciation arising. He thought they would regard this as an exemplary policy, which might be followed with advantage by other manufacturing companies in the City of London. Their head office expenses, including rents, patent expenses, Directors' fees, managing Directors' salary, accountancy &c., stood at £11,423. At their meeting last year the amount of the office charges was challenged. He then said that so far as he was concerned part of his existence was spent in dealing with those charges, and in endeavouring to keep them down as far as possible. They would observe that those expenses during the past year had been £11,423, as against £14,000 odd during the previous twelve months—a proof, he thought, that they had been anxious to keep down the dead charges of the Company. The other expenses, including the cost of advertising, issuing debentures, law charges, &c., were £13,968. This was a considerable increase in the item over the previous year, owing to the fact that this year they had issued debentures, an operation not done without considerable outlay. They might have spread the cost over three or four years, but they preferred to bring it into the current year's accounts, and have done with it. In addition to that there were legal expenses incurred from time to time in ascertaining and maintaining the position of the Company and their patents. He could promise them every vigilance on the part of the Board to keep these expenses down; but he could not promise them, while competition was so keen on the part of their opponents, always willing to take fair and unfair advantage of the Company, that their legal charges would be very much reduced. A company like this existed by proving its capacity for fighting the rights of its shareholders with respect to the properties in which they were interested. This, of course, involved expense. He would now refer to some paragraphs in the report. The report mentioned that they had earned £46,000, after writing off £20,000 against depreciation and after spending £3,000 in preventing depreciation; and out of that £46,000 they had carried £10,000 to reserve, leaving a balance of £35,166. They then referred to their transactions during the year—some of the most interesting work which any Board could undertake—he referred to the development of the electro-chemical patents, for which they were indebted to the skill and ability and ingenuity of Mr. Parker. Their experience in this instance had been that instead of purchasing, as was often the case, for less than they had bargained for they had practically purchased a great deal more than what they bargained for. This electro-chemical business had been growing so much that they had thought it wise to place it in the hands of a separate Company; and their friend Mr. C. Ebbsmith, who had been Managing Director of this Company from the beginning, and had obtained considerable experience in dealing with the electro-chemical patents, elected to become the presiding genius of the process. He might mention as an illustration of the Company that during the last few days they had sold one of the electro-chemical patents for, in hard cash, close upon £30,000, and contingent profits of many tens of thousands more. That had been largely owing to the fact that Mr. Ebbsmith had been able to devote himself exclusively to the work. In all matters of the kind they could not have too much subdivision of labour, and the business in connection with the chemical patents was one by itself, claiming the energy and occupying the time of the ablest man they could put to it. They found that they were not holding their own with storage batteries; and their friend Mr. Courtenay, whose life had been identified with storage batteries, agreed that if they would give to his Company a licence for dealing with storage batteries, he would take up the matter as distinct from the other operations of the Company, and the result had been that the business had been sandwiched in between, and went side by side with, all the other details of that great manufacturing establishment, resulting in very large profit; since it had been placed in separate hands. He would like to express his thanks to Mr. Courtenay for the services that he had rendered and was rendering to the Corporation. The retirement of Mr. Ebbsmith, and his assumption of the position of Managing Director of this electro-chemical branch of their business, involved a considerable readjustment of the office staff; but he was pleased to say the office was now being worked most successfully, vigilantly, and economically under the direction of their friend Mr. Samson, who had been appointed secretary and chief accountant of the corporation. He wished to refer to the services of Mr. Parker. In addition to supervising the works at Wolverhampton and having to deal with a large body of men, and make them willing and anxious to help in promoting the Company, that gentleman had also taken an active part in making the patents merchantable. Moreover, Mr. Parker was consulted every day by people who had big electrical works to undertake, being recognised as the greatest living authority in respect of the manufacture of electricity. They had many items in the balance-sheet, but none representing Mr. Parker. He thought it would have been a good feature to put down a large sum as representing that gentleman. The biggest electrical work entered into in this country was the Liverpool Overhead Railway, which was being worked its entire length by electricity. That Company invited applications from the most eminent electricians in the country to supply an installation for equipping and working that railway; and in open field and with no favour the directors selected Mr. Parker's plan, and the Corporation was now carrying it out. They believed that it would be a large and profitable contract from what was really the first *bonâ fide* electrical railway started in this country. They were also, as the report stated, dealing with the question of the electric lighting of the city of Oxford. There they had accepted a contract from the Corporation to light the city, and he imagined there was no place in all England more suited for electric light installation than Oxford, by reason of the large number of colleges and other institutions perfectly ready and eager to adopt the electric light. It was, besides, a prosperous city, with a great deal of work in it. They were also supplying plant to the Crystal Palace. He supposed if there was any part of London where the electric light could be supplied with profit, it would be in the neighbourhood of the Crystal Palace. They set aside last year £15,000, and this year £10,000, making £25,000; they had written off their capital account £3,000, and for depreciation of machinery they had transferred to profit and loss account £20,000, and reduced their capital charges from £312,816 to £289,716. The only item which might be challenged, and to which he referred, was "shares in subsidiary companies at par, shares included in the original purchase at normal value, and debts due by subsidiary companies, £241,123." He had looked over the figures and he found that the companies there referred to had either paid or were about to pay a dividend, so that the shares were a good investment *per se*. But in addition to that, the fact that they held those shares was a recommendation, and enabled them to secure all the business which those companies might bring to them. With the enormous amount of competition that prevailed they must from time to time acquire an interest in large companies that had orders to give. The investments on their own merits had yielded, or were about to do so, a dividend, in addition to their having been the means of bringing large orders to the Company for which they were not bound to give competition prices, which was too often the case. He would like to read a letter which he had received from an eminent authority on electrical matters. "Another novel branch of electrical industry is the application of electricity to the electro-dissociation of metal and other substances. I am assured that it will not be long before electricity may achieve in a simple chemical manner most of the results hitherto attained by the ancient form of chemistry by the application of a costly and complex process. Already much has been done to this end. Practical men of business are satisfied that electricity is not merely a luxury, but that it has become a commercial power. The Electrical Construction Corporation are, I am sure, much indebted to Mr. Parker for his early researches and inventions in this line. The value of his patents is now undoubted. The profits which the Electrical Construction Corporation or subsidiary companies may make from the sale of patents or licences to use them is an important part of the question, but even more important must be the increased demand for the heavy class of electro-chemical machines required for the development of the power," &c. That was the opinion of a very competent gentleman on the electro-chemical patents. He ought to add that since the publication of the report they had been negotiating for a very important electrical undertaking. He had told them what they were doing in Liverpool, but in addition to that they had been approached by one of the leading tramway companies which had decided on electric traction, and had offered a contract which the Directors were now considering, for erecting the installation

Digitized by Google

—an overhead installation—which would enable the British public to see the possibilities of electricity. He could not say whether they would accept the contract, but whether they did so or not it was one which would involve a great deal of expenditure. They were at the present moment working at high pressure. They were full of work and full of contracts. He did not think a report was ever issued which contained more hopeful statements than theirs. To have paid 6 per cent. for the first year, and to recommend it for the second; to have got their business into a more efficient state, and to have secured the necessary discipline in their very large staff, had been no light task for the Directors during the last twelve months. He concluded by moving the adoption of the report and accounts.

Sir DANIEL COOPER, Bart., seconded the motion.

Mr. HANCOCK desired to have more information as to the terms of the licence with the Electrical Storage Company, and more proof of the value of the shares of the subsidiary companies.

Dr. DRYSDALE wished to know whether it was likely that London was to ever get the benefit of electric traction. He could not understand why they had not got it, and why Liverpool should in this respect be next to New York.

Mr. OLDRITCH thought they were very much indebted to the Directors for the very able manner in which the affairs of the Corporation had been conducted, as was evinced by their ability to pay a dividend of 6 per cent., which he considered very good.

The CHAIRMAN said that the licence to the Electrical Storage Company was not given until they found that their sale of accumulators was declining, as he had told them. They found that their interests at Wolverhampton clashed with the sale of accumulators, and so they handed over the business to Mr. Courtenay. They had made every inquiry, and came to the conclusion that it was the best thing to do, and they secured for themselves with fixed charges a fixed remuneration of £9,000 a year, which was a handsome sum. With regard to the particulars as to subsidiary companies, if any gentleman went to the office Mr. Samson had instructions to afford him all reasonable information; but they were dealing with competitors, and it would be the height of folly to show their hand altogether. It was a question of confidence in the Board; if they had no confidence in them, no information that could be supplied would satisfy them. When he joined the Board he made it a consideration of his doing so, that they should not only have a trained staff, but a continuous audit. Every farthing was subject to a continuous audit by one of the best firms in the City, who examined the accounts from day to day and week to week. He quite agreed about the desirability of getting electric tramways started in London, but there were several reasons why it had not been done. The people who had been working the tramways for years did not wish to introduce a new interest, a new development; and local authorities were difficult to deal with. He did not suppose they would ever succeed in getting an overhead wire system. If they wanted to see how cheaply it could be done, it must be by that system. As to the unpaid calls, they were not losing money by these, because they charged interest on them. He believed that it would be very difficult, indeed, to find a more honestly-earned dividend.

The motion was carried unanimously.

The CHAIRMAN next proposed the declaration of a dividend at the rate of 6 per cent. per annum.

Mr. J. IRVING COURTENAY seconded the resolution, which was agreed to *nem. con.*

The CHAIRMAN proposed the re-election of the retiring Directors, Sir Henry Mance and Messrs. Ebbsmith, Holt, and Moseley.

Mr. JOHN B. VERITY seconded the motion, which was agreed to.

The CHAIRMAN next moved the re-appointment of the auditors, Messrs. Broads, Paterson, and Co.

Mr. JAMES PENDER seconded the motion, which was carried.

Mr. WILLIAMS moved the following resolution, of which he had given notice:—

"*That the Directors shall, in conformity with the power given them by Clause 128 of the Articles of Association of the Corporation, pay half-yearly an instalment on account and in anticipation of dividend.*"

"*That the Directors be requested, with a view to keep the shareholders informed of the position and prospects of the Corporation, either to hold half-yearly meetings, or, this failing, to forward to each registered proprietor in April of each year a short resumé of the Corporation operations for the previous six months.*"

Mr. HANCOCK seconded.

The CHAIRMAN said that the Directors were extremely anxious to pay an interim dividend. They had power under the Articles to do it, and they would not fail to exercise that power when they were in a position to do it; and he would, therefore, ask Mr. Williams to withdraw his resolutions. Every farthing of their money they wanted to use in the Corporation. If they could double their capital they could more than double their profits; and, inasmuch as the declaration of a dividend involved a very serious amount of investigation and examination of their plant at Wolverhampton, he would ask Mr. Williams not to press his resolutions.

Mr. WILLIAMS consented to withdraw them.

Dr. DRYSDALE then proposed a vote of thanks to the scientific staff and the Directors.

Mr. WILLIAMS seconded the motion, which was carried.

Mr. T. PARKER replied for the staff, and said that they might be assured that so long as he occupied his present position nothing would satisfy him but the complete success of the Company.

A vote of thanks having been accorded the Chairman, the proceedings terminated.

The General Electric Power and Traction Company (Limited).

The first ordinary general meeting of this Company was held on Friday last, at Winchester House, Old Broad-street; the Right Hon. the Earl of Albemarle presiding.

The SECRETARY (Mr. Thomas Smith) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN, having referred in terms of regret to the unavoidable absence of three of the Directors on account of pressing business engagements and ill-health, said: Gentlemen, this is our first meeting, and when one rises to address a first meeting it is natural that one should carry one's mind back to the time of the inception of the undertaking in which we are concerned. We began, as you know, from very small beginnings. Our numbers were very few. We did not appeal to the public. Those who have promoted this Company were not professional promoters in any sense of the word, but believers in a form of electrical application which I think we are now seeing gradually developed to the point of success. We began at Brighton with a small experimental installation; and I am bound to say that at its inception we committed as many mistakes as was to be expected under the circumstances. Every mistake was an object lesson; every mistake suggested its own remedy and its own cure; and gradually, by dint of never shirking a difficulty, never trying to evade an obstacle or get round it, but simply boldly meeting it, we found ourselves in a position three years ago to go to one of the most prominent metropolitan tramway companies, and tell them that we were able to show them that electric traction could compete commercially with horse traction, which had hitherto been the rule on their lines. We were fortunate enough, principally through the instrumentality of my friend Mr. Robert Macpherson, who is very intimate with several of the Directors of the North Metropolitan Tramways Company, we were fortunate enough to inspire them with a little of our own confidence; and the result was that we were allowed to run on a small section—two miles—of their line, which extends for 41 miles, to run a certain number of cars, under their supervision. Now, the arrangement that we made with them was that they should pay us 4½d. a mile. We were not quite sure at that time what it would cost; but we were quite certain, with the publicity which would be given to electric traction and the success which we hoped would attend our efforts, that it would be worth our while to try it. Part of the arrangement was that we should bear the cost of the initial work, and that every shilling that was spent should be expended under the direct supervision of the North Metropolitan Tramways Company, that nothing should be done without their direct cognisance, but that we should not be impeded in our operations. We did that in order that we might be able to appeal to accomplished facts. At the inception of our undertaking we were not in a position to glorify ourselves, and to say that we could do this and that; and we desired to be able to appeal to an independent company of unimpeachable character to say whether the statements we submitted to the public were justified or not. For three years we have been working on the Canning Town section of the North Metropolitan Company's tramways. From the very first we found the very greatest kindness on the part of that Company, and a great disposition to encourage us in our advances, and to help us in every way in their power, and to grant us their full confidence. I am happy to say that we have succeeded on that line very well—so well, indeed, that in the year 1889 the North Metropolitan Company found themselves in a position to apply to Parliament for permission to extend over their whole system electric traction, and entirely do away with horses. Parliament granted the request, and gave them seven years in order to form a reasonable basis on which they might raise the necessary capital and pursue their operations. We thought that everything was going on well. We satisfied the Company with whom we were contracting. We inspired them with the same confidence as ourselves; and we had obtained from Parliament, as we thought, what would extend over a large part of the metropolis the advantages of the electric system of locomotion. Unfortunately, the West Ham Corporation were of opinion that they ought to have a veto upon the construction of electric tramways throughout their district, of such a character that made it quite impossible to proceed with the work under these terms. They had no objection to the seven years, and were willing to let us have the opportunity of showing to the electric world electric traction in full operation. But I hardly know how or why they thought it necessary to insert in their Act of Parliament a provision that they should have a veto on electric traction at 24 hours' notice. Though Parliament granted seven years, they felt it necessary for their municipal purposes, if they should consider that electric traction was in any way objectionable, that they should be at liberty to give notice to the North Metropolitan Company to remove the whole of their plant within 24 hours. I need not tell you, gentlemen, that when an expenditure of £40,000 was involved, it was quite impossible for any reasonable body of individuals to undertake so onerous a responsibility as that with such a provision hanging over them at the option of a fluctuating body who might call upon them to remove their work within 24 hours. They consequently said that, satisfied as they were that electric traction was a great success, and had been proved so for two years, they must again appeal to Parliament for some modification of the terms under which they were to act. We are in this position, that this Company has renewed with the North Metropolitan Company the contract in a slightly modified form to work a piece of the Canning Town line; but until Parliament intervenes, which I hope it is going to do in the next Session, it is impossible for us to proceed further with that part of our system. We are working without accident, without hitch, and we are working at a less expense than with horses. We have proved our case up to the hilt; but, owing to the unfortunate circumstances I have detailed to you, we are unable at the present moment to proceed with that part of our district in London. That has, of course, affected

Digitized by Google

the immediate returns which we might have expected had a more favourable result ensued. Gentlemen, I am not in the habit of using strong language, or the language of prophecy; but I am bound to say to you that that is no discouragement to your Directors and ought to be no discouragement to you. It is to a certain extent deferring your just expectation; but you will see that it is a matter beyond our control and the control of that very kind and accommodating company with which we have had relations, the North Metropolitan Tramways Company. I hope next year we shall be able to give you better accounts on that point. When a leading company, such as the North Metropolitan, had taken the matter in hand as a test case, and had to declare to the electric tramway world whether or no electric traction was a success, any delay on their part naturally influenced the general body of tramway proprietors; and it was found that we had to wait for other companies to follow their example. But from the enormous number of applications that are constantly being sent to us to introduce electric traction into various towns in the country, we think that there is a very strong feeling arising among users of tramways that electricity is the proper mode to adopt, and many proposals have been made to us to equip tramways in various parts of the Kingdom. But you will also observe that here comes in a perfectly general rule, and that is that tramway companies have usually locked up almost the whole of their available capital in their horse traction, in the cars adapted for horses, in the horses themselves and their maintenance, and in the matter of stables and all the other preparations for their system. Naturally, then, they had not a great command of money; and, though they desire to go in for electric traction, it can only be done on their own account or by making arrangements with electric companies to supply the money. While we thought that there was a future for electric traction, we also considered that we ought not to run any risk in anything which would turn into a speculation, by embarking money for the purpose of equipping tramway lines. Therefore, we have turned a deaf ear to any such proposal, and I hope you will approve the prudence which the Directors have shown with regard to that. It is just as in the case of the delay with respect to the North Metropolitan Company; it has somewhat postponed our ultimate success, but it will make it more sure. It has demonstrated that success will come. I will turn now to another part of our business which has been very largely developed, and which has been successful to a degree which has afforded great satisfaction to the Directors—I mean working in mines and coal winning which is more recent than pumping. Electric pumping in mines has been developed to a very considerable extent, and has employed our works in a very satisfactory manner, and with fair returns. But that, like the whole of the electric industry, is still in its infancy, and we hope to see it very largely developed. But we have very great confidence in it. I believe we have a very considerable percentage of all the electric hauling that is done in mines in our hands—75 per cent., I believe; but I won't pledge myself to that, preferring to leave that to experts—but I think we have a very fair proportion of such work as is done in mines by electricity; and from indications that are constantly coming before us, we may say that the mining interests are coming more and more to believe in the feasibility and the economical qualities of electricity, that we shall have an extension in that direction. There is another point to which we have considerably devoted our attention—that is, electric boats. Now, with respect to them, I must say that we stand alone. We have got a large fleet of boats already on the Thames, started by Mr. Immisch and continued and developed by his successors, this Company. It is daily increasing. We find that foreign Governments are coming to us for electric propulsion to be applied to boats. We have hopes that the English Government will come to us, but it is not so quick in its movements as some other Governments are. At any rate, we are acquiring a very considerable amount of confidence among the users of electric launches. We have gone into the question of the electro deposition of copper and we find there a larger possibility. I must say that all that I have been able to learn, and all that my colleagues have been able to learn, on this point, that in entering into that industry we are embarking on something which ought to give very good results. As I said, I never like to indulge in the language of prophecy; but I must confess to entertaining considerable confidence in my own mind, and I think I speak for my colleagues as well—of the success of that branch of business. Then there is the general question, we are purveyors of electric plant. They say that a prophet has no honour in his own country; but lately the St. Pancras people round our own works have got an electric installation for lighting their district, and I am happy to say that the confidence which has been shown by the people in that district in their immediate neighbours, the works of this Company has been very great, and we have been called upon to supply the electric fittings for the installations in the St. Pancras district. I think that is an encouraging thing, because it shows the feeling which exists among our immediate neighbours, and their capability of appreciating our work. I do not think that I need detain you longer, but my friend the general manager reminds me that we have sent out general estimates amounting to £400,000, of which £150,000 in orders have been promised next year. There are places where the Corporations themselves have taken into their consideration the advisability of adopting electric traction for the municipal tramways; and in those cases the difficulties I have described in the case of the West Ham Corporation, and in the case of tramways generally, will not occur, and I am happy to say that we are in intimate connection and negotiation with some very large Corporations who are proposing to alter their mode of traction to electricity. Though it would not become me to speak with any positiveness about anything which is not actually concluded, the shareholders will at once see that it is necessary prudence on my part. I hope that next year I shall be able to give you a very good account of that part of our business. Subject to any questions which may be asked by the shareholders, I will conclude by moving:—

"*That the report and accounts be adopted, and that the agreed dividend of 7 per cent. on the preference shares be hereby declared, and that the same be payable on January 22, 1892*"

Mr. THOMAS FULLER seconded the motion, which was agreed to without discussion.

Mr. TURNER moved:—

"*That Messrs. Ward and Wilding be re-elected auditors to the Company, the remuneration being fixed at fifty (50) guineas.*"

Mr. C. KING SMITH seconded the motion, which was also carried.

Mr. EBB-SMITH proposed a vote of thanks to the Chairman and Directors, which

The CHAIRMAN briefly acknowledged; and the proceedings terminated.

Fowler-Waring Cables Company (Limited).

The third ordinary general meeting of this Company was held on Thursday, December 17th, at Winchester House, Old Broad-street, Mr. William Fowler presiding.

The SECRETARY (Mr. D. Stephen) having read the notice calling the meeting,

The CHAIRMAN said: I have now to move:

"*That the report and accounts, as delivered, be received and adopted.*"

In doing so I wish to say, in the first place, that I am very sorry that Mr. Chamberlain, one of our most active and useful Directors, is ill, or he would have been present with us. He writes me to say that he wishes me to express his great regret at his absence, and his entire confidence in the future of the Company. I have also a letter of the same tenor from Mr. Gathorne-Hardy, who is unavoidably detained in the country. Now, gentlemen, our report is so full as regards the actual condition of the Company, combined with the report of the Manager, that it is not necessary for me to detain you at any length. We have expressed regret—and I feel very much regret—that we have not been able to declare a dividend this year, but I can hardly say that I am greatly surprised, because it is just one of those businesses which take some time to develop, and therefore we cannot expect to obtain a dividend exactly as we should in many other kinds of business. I wish also to say especially that all business of this kind—every business, in fact, but this kind of business especially—depends on management. Now, when I was here a year ago almost exactly, I expressed my confidence in the management as it had then just been settled. Our present manager had, I think, been five months in office when we met last year; and I wish again to express my still greater confidence in him, and my sense of the energy and ability which he has shown in the management of the affairs of the Company. And I think that those who know him outside the Company will not be surprised at my making that statement. Now, what you will say is: "That is all very well, but we want to know what you think about the prospects of the Company?" Well, gentlemen, I expressed myself with satisfaction last year at the belief and hope that our prospects were good. What I said has been fully borne out. We have had a great increase in the business of the Company, and we see before us immediately, I think, a still further increase: and I have really great hopes—I think I may say an expectation—that if we are all alive and well next year we shall have something very satisfactory to report, and not merely something to report, but something to divide, which is a great deal more satisfactory than anything that might be reported. We have large additional orders coming in at the present time, and the inquiries are numerous and important. I am very careful when I occupy this position not to overstate things or to hold out expectations which are not likely to be realised; but I feel confident that this Company, notwithstanding all the difficulties that it has to meet, in great competition and the continual changes that take place, owing to inventions in electrical affairs—I feel confident that, notwithstanding all these peculiar difficulties, we shall have, with the kind of management we have now, a prosperous year; and not only a prosperous year, but, I hope, many prosperous years. I do not think that I need detain you with any more details. The accounts speak for themselves. We have explained everything on the face of the accounts, and any shareholder who has studied them can understand them. Still, if any question occurs to you to ask I shall only be too happy to hear it. I repeat my great regret that we have not something to give you this time, but I say again that I feel great confidence in the future of the Company. I now beg to move that the report and accounts be received and adopted.

Mr. GEORGE FLEMING: I second that.

The CHAIRMAN: If any gentleman has any question to ask, I shall be happy now to hear him. No shareholder rising, he put the motion in the usual way, and declared it carried unanimously. Continuing, he proposed the re-election of Mr. Walter Chamberlain and Mr. R. W. Eddison to their seats at the Board.

Mr. R. S. WARING seconded the motion, which was carried unanimously; and Messrs. Cooper Brothers and Co. were afterwards re-appointed auditors to the Company.

The CHAIRMAN: I should just like to add that Mr. Eddison has lately been to America, and has spent a great deal of time there—and I think usefully—in the interests of the Company in finding out what is going on, and obtaining information which will be of great value to us. I believe that is the whole of the business of the meeting.

The proceedings then terminated.

British Tanning Company.

The annual general meeting of the shareholders of the British Tanning Company (Limited) was held at Winchester House on Friday last; Mr. Adolphus Horny presiding.

Mr. H. HODGES (the Secretary) having read the notice convening the meeting,

Digitized by Google

The CHAIRMAN said he should like to go a little into the accounts, and to compare some of the figures with those of last year. The stocks in hand in 1891 amounted to £1,157, against £2,262 the year before, showing a diminution of £1,105. The purchases of raw materials were this year £2,365, against £5,662 in the previous year, or £2,297 less than before. The sales of manufactured goods amounted to £3,431, against £1,804 last year, showing an increase of £1,627 during the year. Salaries, wages, and office expenses, which came to £1,002, represented a reduction of £700. The law expenses had been £1,086, as against £424 the year before, or an increase of £662. He would go into this item more fully presently, because it was one of the principal items in the account. They had written off 25 per cent. for depreciation of plant. In the first year they did not write off anything on that account. The share capital was practically the same as last year. The amount of £20,000 which was down as having been paid to vendors under agreement had not been paid in cash. The greater part had been paid in shares, and only a small portion in cash, which showed that the inventors had great confidence in the Company. The balance to profit and loss account was £3,809, as against £5,230 the year before, or a reduction of £1,421; and when an allowance had been made for the heavy law expenses of the year, it would be seen that there was a great improvement as compared with the previous year. He would now give the meeting a short sketch of the experience of the Company during the year. He was glad to say they had got out of the lawsuit about which they were informed when they met the Directors in December, 1890. As they were aware, the Directors had to vindicate their rights to their patent against a person who had taken out another patent, which, according to the best opinion, was only a slight modification of the patent of this Company. Counsel informed the Directors clearly that that patent was an infringement of their patent, and they were then told by their legal advisers that it was their bounden duty to put a stop to the working of the other patent by commencing a lawsuit. They did so, and the case came before Mr. Justice Romer in January last; but he was sorry to say that it was decided against them, on the ground that the difference between the working of the two patents was sufficient to constitute a new patent for the other process. It was further stated that the Company's own patent was invalid by reason of a prior publication. They then thought that for a time they really had no patent at all, and they had to decide what was best to be done under the circumstances. First they sought to make the vendors in Paris responsible for the loss the Company had sustained, and claimed a return of the amount they had received from the Company, with damages. However, the vendors objected to this course, on the ground that the lawsuit had only been decided in the first Court in England, and the result might not be confirmed in a Court above. The Directors were about to appeal to have this decision reversed, but the Attorney-General advised them that there was not the slightest chance of their succeeding. So, finally, on the advice of their legal advisers, application was made for a special Act of Parliament, which had for its object the reviving of the Company's patent. The Worms and Bale Patent Bill was accordingly introduced into the House of Lords in April, and, despite all opposition, passed both Chambers, and received the Royal Assent on July 28, 1891. Their property had thus been restored to them—a result chiefly due to the exertions of their solicitors. That brought him to a consideration of the position of the Company at the present time. As they all knew, it was very expensive to go to law, and also to get a private Bill passed through Parliament. Therefore there had been a great strain on the resources of the Company, and their manufacturing work could not be carried on upon such a scale as would otherwise have been the case, so as to obtain a profit by it. At the same time they would make the inventors in Paris responsible for a great part of the legal expenses, and they had also reasonable hopes that the money they so claimed would soon come in. In the meantime they had taken process in Paris, which would prevent money going to the inventors from other foreign patents they might sell until the claim of this Company had been settled. The shareholders would now like to know, perhaps, that three such patents had been sold to Brazil, Uruguay, and the Argentine Republic for £50,000. This would prove to the tanning industry in England that other countries appreciated the process adopted by this Company, and should make them regard it with more favour than they had hitherto done. It would thus be seen that they had a valuable patent, that they were in a far stronger position than they were before, and that they had made, and could make good leather in a very short time, as stated in the prospectus. If, however, they were to continue to manufacture it would be necessary to have funds which would enable them to do it on such a scale as they could make a profit out of it. To this end they had entered into negotiations with various parties both at home and on the Continent, and they hoped to be able to obtain the assistance they required. But for the present they did not want any further capital, and they would not decide anything without calling the shareholders together and obtaining their authority. They would all be sure that the Directors would not ask for further funds until they were confident that the prospects of the Company warranted the adoption of such a course. He would now inform them that they had entered into negotiations with a firm of first-rate tanners to take over the whole of the Company's plant, work it with their own capital, make their own purchases and sales, and prove in that way that the Company's process could be worked under ordinary conditions with a profit in the same way in this country as in others. He believed that such an arrangement was likely to be carried into effect. In conclusion, the Chairman said he could not see why they should not prosper and have as good results as were obtained in Paris and elsewhere. He then moved the adoption of the report and balance sheet.

Mr. DUFRESNE seconded. He could not see why a process which had been proved to have been a complete success elsewhere should not also be as great a success in England. It was in consequence of the experiments which had been made that the South American patents had been sold. The difficulty with which this Company had to contend was vested interests, but he had little doubt as to its ultimate triumph.

Mr. RIDLE, a shareholder, asked for some further information relative to the solicitors costs.

The CHAIRMAN said the solicitor's bill for law expenses to June 30th, including those of the lawsuit, amounted to £1,305, of which £250 had been paid. £652 10s. would have to be paid by the Paris inventors, quite irrespective of the expenses of obtaining the private Bill in Parliament, which amounted to £690. Altogether, therefore, the vendors owed the Company in respect of these matters £1,342.

The report and balance-sheet were then adopted, after which the auditors, Messrs. Cooper Brothers and Co., were re-elected.

A vote of thanks to the Chairman and the Board of Directors closed the proceedings.

The Gulcher (New) Electric Light and Power Company (Limited).

The fourth ordinary general meeting of this Company was held at Winchester House, Old Broad-street, on Friday last; Mr. R. Pryor presiding.

The SECRETARY (Mr. T. C. Morgan) read the notice calling the meeting and the minutes of the previous meeting, these latter being confirmed and signed.

The CHAIRMAN explained that the meeting had been called to comply with the statute, and they desired it to be adjourned for two months, by which time the Chairman of the Company, now on his way back from New Zealand, would have arrived and be able to furnish them with the results of his visit. He accordingly concluded by proposing a motion to that effect.

Mr. H. GRÈWING seconded the motion, and it was agreed to.

Elmore's Patent Copper Depositing Company (Limited).

The following is the second annual report of the Directors of this Company to the 30th June, 1891, to be presented to the shareholders at the Cannon-street Hotel, on Wednesday the 30th December inst., at 12 o'clock:—

The Directors have pleasure in submitting to the shareholders their report, and in congratulating them on the satisfactory technical and commercial prospects of the Company. The accounts show a credit balance at the end of the preceding year of £77,825. 1s. 4d., from which two dividends of 10s. each, making £1 on each £2 share, were paid. It will be seen from the accounts, which accompany the report, that there were credit balances on June 30th last of £14,261. 17s. 10d., made up of £5,000 royalties on copper sheets received in advance, £8,558. 7s. premiums and profit on land, and balance of profit and loss of £703. 10s. 10d., a satisfactory result considering that the Company had only been able to manufacture small quantities of articles at the date of making up of the accounts—work on a large commercial scale not having been then commenced.

The Directors have much satisfaction in announcing the successful completion of the 20-ton plant, and thus the programme of work set forth in the prospectus has been carried out. The cost of manufacture has also now been found to be only about ½d. per pound weight of finished goods, that is to say, about one-half the cost that the Directors estimated in the prospectus, whilst the statements as to the technical features of the process have been entirely proved. The Directors are the more gratified in being able to refer to these results, as, though the application of the essential part of the Messrs. Elmore's invention has remained unchanged, various difficulties connected with the mechanical details of the process, inseparable from the commercial development of all important inventions, were encountered. These caused some considerable delay.

The Managing Director reports that all these difficulties have now not only been successfully overcome, but that they have led to the taking out of additional patents of great value, which will have the important practical effect of prolonging the monopoly of the invention. Foremost amongst these may be mentioned the patent for the manufacture of sheet copper, the licence to work which on a royalty, which will prove a valuable source of income to this Company, has been granted to Elmore's Wire Manufacturing Company.

The Directors desire specially to draw the attention of the shareholders to the purchase of the Haigh Park Estate, Leeds, consisting of 127 acres of freehold land, on a portion of which site the Company's works have been erected. The purchase of this property was rendered advisable by the impossibility of acquiring portions of it required for the purposes of the Company and its future extensions, except at the price of £2,000 per acre, whereas the price actually paid for the whole estate was only £534 per acre, including all expenses. The land is within half a mile of the Borough of Leeds, connected by sidings with the Midland and Great Northern Railways, and has a wharf on the Aire and Calder Canal, which latter bounds the estate for three-quarters of a mile. It has an extensive frontage to the Pontefract high road, and is in close proximity to cheap coal supplies. The new line of the South Leeds Junction Railway, for which a Bill has been lodged in Parliament, is planned to run through the estate. These advantages and improvements have resulted in what the Directors foresaw, viz., a great increase in the value of the land, which must make the purchase a valuable acquisition for the Company. Negotiations have already taken place for the sale of portions at a considerably higher

Digitized by Google

price than that paid. A plot of 13 acres has been disposed of at £1,000 per acre to Elmore's Wire Company; and this price, whilst yielding an excellent profit to your Company, is nevertheless 50 per cent. below the price demanded for this plot by the former owner, and the Directors are advised that they will be enabled to dispose of the whole of the land not required for the purposes of the Company at a similar profit.

The completion of the 20-ton plant was lately marked by an invitation to the larger shareholders to see it at work, and over 100, from various parts of the country, availed themselves of this invitation, and they expressed the greatest satisfaction at what they saw.

The Messrs. Elmore have made a joint report to the Board as to the earning-powers of the works. This report is of a most important character and is enclosed herewith. By this report it will be seen that the profits of the works as now completed are put at over £45,000 per annum, being 30 per cent. upon the present capital of the Company, whilst when the time comes for doubling the output to 40 tons per week the profits will be increased to over £95,000 per annum, equal to nearly 50 per cent. upon the increased capital that will then be required. These returns, extraordinary as they may seem, Mr. Elmore fully believes will be exceeded by actual results; and considering that the report takes no account of important sources of profit such as sales of licences, recovery of precious metals, and special kinds of work, the Directors see no reason to doubt the conclusions therein contained.

From the numerous testimonials from important firms, copies of some of which have already been despatched to the shareholders, it has been shown that the goods supplied to customers have given complete satisfaction, and of this the numerous repeat orders, and the offers of a very large additional business at remunerative prices, are a still better and more practical proof.

The Directors desire, in conclusion, to record their belief that, now that the Company may be considered to have entered upon its legitimate manufacturing business on a commercial scale, the shareholders will find that in the Elmore invention they possess a process that will be a continual source of profit, increasing from year to year, as the quality of the goods produced becomes more and more known.

The Directors who retire are Sir John Morris, Mr. Atkinson, and Mr. Carson; the former, owing to continued ill-health, does not seek re-election; the latter two are eligible, and offer themselves for re-election. The auditors, Messrs. Price, Waterhouse and Co., also retire and offer themselves for re-election.

A report by the Messrs. Elmore accompanies the Directors' report and accounts, from which we learn that the Messrs. Elmore confidently anticipate the eventual earnings of the Company to return *over 50 per cent. per annum*. The following also accompanies the copy of the report we have received:— "Since the Directors' report was made out, the result has been received from Leeds of an important competitive trial that has just taken place of an Elmore tube, nine inches in diameter and one-eighth of an inch thick, against the best brazed tube obtainable of similar size made by the ordinary system. The tests showed that the brazed tube burst in an uneven manner at 448 lbs. pressure. The Elmore tube stood at 1,456 lbs. pressure, being over three times as strong, and then gave way gradually and evenly. Some idea may be formed of the strength of the Elmore tube when it is mentioned that the testing machinery had to be specially prepared, owing to the enormous resisting power of the Elmore tubes."

Elmore's Wire Manufacturing Company (Limited).

The following is the first annual report of the Directors of this Company, and is for the period from March 15, 1890, to October 31, 1891; to be presented to the shareholders at the Cannon-street Hotel, E.C., on Wednesday, the 30th inst., at three o'clock.

The period with which this report deals has been devoted entirely to the erection of the Company's works upon thirteen acres of freehold land purchased from the Parent Company and immediately adjoining that Company's works. The main building consists of a series of bays, each 400ft. long by 35ft. wide, having a total width of 350ft. under one roof, and covering a space of about 3½ acres. These buildings have been designed with a view to an output of 140 tons per week. There are also offices for the staff and Managing Director complete in every respect, together with convenient store and packing shed, with sidings from the Midland and Great Northern Railways already connected up therewith. [The actual progress made at the works is here set out in the report.]

It will be seen (the report proceeds) that the works will make a start with an output of about 35 tons a week. This can be readily increased up to 70 tons a week with little additional expenditure above that already incurred.

The Company has also acquired from the Parent Company, upon a moderate royalty, the sole licence outside the requirements of the Parent Company, for the manufacture of copper sheet, under a patent taken out by the Parent Company last year; and the Board consider, in view of the large demand for copper sheet, that this licence will prove of great value.

Since the Company was formed, and the buildings commenced, the Directors have learned with satisfaction that the whole of the proposed output can be readily disposed of in the form of ribbon or tape, and planished sheet, at a profit considerably in excess of that estimated from the sale of wire spirals. The Company will therefore neither erect wire-drawing plant on a large scale for the present, nor dispose of its copper spirals to wire-drawers, thus adding to the gross earnings of the Company one manufacturing profit.

Mr. Elmore, Managing Director, reports that early in the year 1892 the Company will be in a position to commence with an output of 35 tons per week.

In regard to the accounts, which accompany the report, these are exceedingly simple; inasmuch as no trading account having yet been opened, the only outgoings beyond capital expenditure are those occurring under administration expenses, which, however, have been reduced by one-half, largely in consequence of the satisfactory profit derived from a judicious investment last year in Consols and Bank of England Stock.

The auditors, Messrs. Deloitte, Dever, Griffiths, and Co., offer themselves for re-election, and the Directors recommend a payment to them of 35 guineas for their services.

NEW COMPANIES, STATUTORY RETURNS, &c.

BEDFORD AND KEMPSTON TRAMWAY COMPANY (LIMITED).—This Company was registered on December 17, 1891, with a capital of £10,000, in £10 shares, by Barnard and Taylor, 47, Lincoln's Inn-fields, London. The objects are to construct, purchase, lease, or otherwise acquire any tramway or tramways in the parish of St. Paul and St. Mary, in the Borough of Bedford, and in the parish of Kempston, in the county of Bedford, and to equip, maintain, and work by animal, steam, electrical or other mechanical power all tramways belonging to the Company.

FIRE EXTINGUISHING COMPANY OF INDIA (LIMITED).—This Company was registered on December 14, 1891, with a capital of £2,500, in £1 shares, by Busk and Co., 45, Lincoln's Inn-fields, W.C. The Company has for its objects the purchase and acquisition of certain patents, patent rights and inventions for, or in connection with an electric fire indicator and suppressor, and to work and develop the same.

JOHN WILKES, SONS, AND MAPPLEBECK (LIMITED).—This Company was registered on December 14, 1891, with a capital of £250,000, in £5 shares, by Waterlow, Brothers and Layton (Limited), Birchin-lane, London, E.C. The objects are to purchase or otherwise acquire as going concerns the businesses of copper smelters, refiners, manufacturers of brass and copper sheets, tubes, wires, and rolled metal, heretofore carried on in Liverpool-street and Abberley-street, both in the City of Birmingham, under the respective styles of "John Wilkes and Sons," and "John Wilkes, Mapplebeck and Co.," and to carry on the business of copper smelters and refiners, brass founders, metal workers, iron and steel converters, mechanical engineers, &c. Registered office: Liverpool-street, Birmingham.

SOMERTON, KEINTON-MANDEVILLE, CASTLE CARY, AND EVERCREECH TRAMWAYS SYNDICATE (LIMITED).—This Company was registered on December 14, 1891, with a capital of £1,500, in £50 shares, by Hargreaves and Co., 9, Bridge-street, Westminster, S.W. The objects are to acquire and take over the consents obtained by the Local and Road Authorities to the construction and maintenance of a tramway, and the use of steam, electrical and other mechanical power thereon, from Evercreech to Castle Cary, thence to Keinton-Mandeville, and thence to Somerton, and to equip and work the said tramway. Registered without Articles of Association.

BLACKPOOL ELECTRIC TRAMWAY COMPANY (LIMITED).—The annual return of the above-named Company, made up to December 12th, 1891, was filed on the 17th following. This Company was registered on January 24th, 1884, with a capital of £30,000 in £10 shares, to work what was called Holroyd-Smith's Patent. At the time of making-up, the whole of the shares had been taken up, 150 of which had been issued as fully paid. Upon the remaining 2,850 £6 10s. per share had been called, resulting in a payment of £18,525. Registered office: Albert-terrace, opposite Bailey's Hotel, Blackpool.

CHELSEA ELECTRICITY SUPPLY COMPANY (LIMITED).—An agreement was made on November 7, 1889 (and filed on December 15, 1891) between the above Company (referred to as the Chelsea Company) of the one part, and the Callender's Bitumen Telegraph and Waterproof Company (Limited) (referred to as the contracting Company) of the other part, which states that, whereas the contracting Company has agreed to supply certain goods, and to do certain work in the event of its being required to the Chelsea Company, it is therefore agreed that the contracting Company shall, upon receipt of a notice in writing within six calendar months from this date, supply, deliver, and fix in working order, at such places in Chelsea or Kensington as the Chelsea Company may direct, the plant described in a specification signed by two Directors and the secretary of each Company. In consideration of the supply, delivery, and fixing of the said plant, the Chelsea Company shall pay to the contracting Company £1,520, one-third of which shall be paid in cash, and two-thirds in fully paid-up shares or in cash at the option of the Chelsea Company, and the contracting Company agrees to accept the said shares and cash in full payment for the said work and plant. By an agreement made December 15, 1891 (and filed on the same day) between the same parties, the work mentioned above having been completed to the satisfaction of the Committee of consulting engineers of the Chelsea Company, who have signed a certificate, dated December 7, 1891, to that effect, the contracting Company agree to accept the allotment of 304 fully paid-up ordinary £5 shares in the Chelsea Company, numbered 7,908 to 8,211, both inclusive, in full satisfaction for the supply of the said plant and the work done. The above named Company was registered on November 18, 1884, with a capital of £100,500, divided into 20,000 ordinary shares of £5 each, and 500 founders' shares of £1 each. The Directors in 1888 were the Right Hon. Lord Thurlow, J. I. Courtenay, Esq.; Nugent Daniell, Esq., Sir George R. Prescott, Bart., and Major-General C. E. Webber, C.B. Present registered office: Draycott-place, Chelsea, S.W.

GLOBE ELECTRIC COMPANY (LIMITED).—The following was filed on December 14, 1891:—An agreement made November 30, 1891, between Sir William Vavasour, of Hazlewood, Yorkshire (called the vendor), of the one part, and the above-named Company of the other part, states that whereas, by an agreement dated November 30, 1891, between the same parties, the Globe Company agreed, in consideration of the assignment of certain patents, to issue to the vendor 5,500 fully paid up shares of £1 each, it is agreed that the Company shall, before December 1, 1891, allot to the vendor or his nominees the 5,500 fully-paid up £1 shares in the purchasing Company. The above-named Company was registered on November 4, 1891, with a capital of £10,000, in £1 shares. Registered office: 36, Great James-street, Bedford-row, London, W.C.

GORDON ELECTRIC TRACTION SYNDICATE (LIMITED).—The annual return of this Company, made up to December 9, 1891, was filed on the 17th following. The Company was registered on August 13, 1890, with a capital of £2,400 in £10 shares, to purchase the invention of John Gordon of a system of electrical car traction, and the provisional protection for the same, dated May 5, 1890, and numbered 6,083, and to work and develop the same. At the time of making up, 206 shares were taken up, of which 60 were issued as fully-paid. On 133 of the remainder, £10 per share had been called, and on 13 £5 per share, resulting in a payment of £1,395. Registered offices: the offices of Messrs. Merryweather and Sons, Greenwich-road, Greenwich, Kent.

NATIONAL TELEGRAPH WORKS COMPANY (LIMITED).—By an agreement dated December 7, 1891 (and filed on the 12th), between J. Slater Lewis, telegraph engineer, of the one part, and the Company of the other part, the vendor agrees to sell and the Company to purchase the interest in an invention of an improved method of manufacturing window sashes or frames; and also the business of manufacturing electric, telegraph, telephone, and railway instrument batteries, and other electric appliances as carried on at the National Telegraph Works, 109, Wainwright-street, Aston, near Birmingham. The purchase price to be paid to the vendor for his said invention and the goodwill of the said business shall be 35 fully paid-up founders' shares of £1 each. For the other property agreed to be sold, viz., the net balance of assets over liabilities, to be ascertained by the auditors of the Company, the vendor shall accept fully paid-up ordinary shares. The vendor, so long as he is able and holds at least 150 fully paid-up shares, shall be managing Director for five years from August 24, 1891, with a salary of £250 per annum, and an additional £50 per annum for each 2½ per cent. up to 7½ per cent. paid as dividend. A supplementary agreement to the above, made December 11, 1891 (and also filed on the 12th) between the same parties, states that whereas Messrs. Rhodes and Co., chartered accountants, of 34, Waterloo-street, Birmingham, have ascertained the net balance of assets over liabilities, due to the vendor, as the purchase price for the property to be £525, it is therefore agreed that the total amount due and to be paid to the vendor is as follows:—(1) The purchase price for the invention and goodwill of the business, 35 fully paid-up founders' shares, numbered 1 to 35 inclusive, to be allotted to the vendor; (2) purchase price for the other property agreed to be sold at the net balance of £525, ascertained as aforesaid, to be satisfied by the allotment of 105 fully-paid ordinary shares of £5 each to the vendor; and (3) the debit balances found to be due from the vendor in respect of the said invention, business, plant, machinery, articles, and things mentioned in the principal agreement, £1,799. 10s. 6d., the total purchase consideration being £2,359. 10s. 6d. Registered office: 109, Wainwright-street, Aston, near Birmingham

NEW TELEPHONE COMPANY (LIMITED).—The following notices were filed on December 14, 1891:—At an extraordinary general meeting of the members of the above-named Company, duly convened and held at 90, Cannon-street, in the City of London on November 6, 1891, the following special resolutions were duly passed, and at a subsequent extraordinary general meeting of the members of the said Company, also duly convened and held at the same place on November 25, 1891, the following special resolutions were duly confirmed:—(1) That the existing shares in the capital of the Company be consolidated into 12,000 shares of £10 each. (2) That the capital of the Company be increased from £120,000 to £750,000, by the creation of 62,700 shares of £10 each, and 3,000 new shares of £1 each. (3) That the new regulations submitted to this meeting and intituled "Articles of Association of the New Telephone Company (Limited)," be and are hereby adopted as the regulations of the Company, to the exclusion of, and in substitution for, all the existing regulations of the Company. The new Articles of Association, which were filed with the above notice, states that the capital of the Company is £750,000, divided into 74,700 ordinary shares of £10 each, and 3,000 founders' shares of £1 each. The founders' shares are to be offered for subscription to his Grace the Duke of Marlborough, Mr. R. W. Wallace, and Mr. Charles Davis, three of the Directors of the Company, through whose intervention, and at whose instance, the winding-up of the Company was stayed in 1891, and the Company was enabled to resume business. The number of Directors is not to be less than three nor more than nine, the first being the above-named gentlemen. Qualification, £500. Remuneration, £3,500 per annum, to be divided as they themselves determine. The above-named Company was registered on November 20, 1884, with a capital of £120,000, in £5 shares, to acquire several letters patent for Great Britain for inventions for improvements in electrical apparatus for the transmission and reproduction of sound, granted to Silvanus P. Thompson, or to S. P. Thompson and Philip Jolin jointly, and the first Directors were the Right Hon. Lord Thurlow, the Right Hon. Lord Sudeley, Sir Daniel Cooper, Bart., and John Irving Courtenay, Esq. By an agreement dated May 6, 1885, between the vendors and the Company, S. P. Thompson had 1,000 £5 fully paid-up shares allotted to him in full satisfaction of his proportion of the first issue of shares. At an extraordinary general meeting of the members of the Company, held at 4, Great Winchester-street, E.C., on April 27, 1889, Sir Daniel Cooper in the chair, the following resolution was passed: "That it has been proved to the satisfaction of the meeting that the Company cannot, by reason of its liabilities, continue its business, and that it is advisable to wind up the same, and accordingly that the Company be wound up voluntarily;" and at the same meeting Mr. W. S. Ogle, of 90, Cannon-street, E.C., was appointed liquidator for the purposes of such winding-up. In the High Court of Justice (Chancery Division), on June 1, 1889, it was ordered by Mr. Justice Stirling that the voluntary winding-up of the Company be continued subject to the supervision of the Court. But on July 10, 1891, in the High Court of Justice (Chancery Division), upon the petition of Prof. Silvanus P. Thompson and Emile Garcke, Esq. (of the Brush Electrical Engineering Company, Limited), Mr. Justice North ordered that all further proceedings in relation to the winding-up of the Company be stayed. The last return, made up to January 3, 1891 (filed on September 17, 1891), shows that while the nominal capital was £120,000, in £5 shares, 3,000 shares had been taken up, of which 1,000 had been issued as paid. £5 per share had been called upon the remainder, resulting in the payment of £9,960, while £40 was in arrears. Present registered office: 90, Cannon-street, London, E.C. The official notice, informing the Registrar of Joint-Stock Companies, in accordance with the Companies' Act, 1862, that the existing 24,000 shares of £5 each in the capital of this Company have been consolidated into 12,000 ordinary shares of £10 each, was filed on December 15, 1891.

SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to December 8, 1891, and filed on the 17th following, shows that out of a capital of £1,000,000, in £5 shares, 78,949 ordinary, and 19,750 fully-paid shares have been taken up. Upon the ordinary shares £3. 10s. per share has been called, resulting in a payment of £279,851. 10s. £98,750 is considered as paid, and £3,530 is the total amount paid on 1,201 shares, which have been forfeited. The following are the holders of 500 shares and upwards:—C. Gill, Java Lodge, Beckenham, 500; E. W. Batt, 15, Great Winchester-street, E.C., 550; W. Agnew, M.P., Summer Hill, Pendleton, Manchester, 1,000; T. S. Allpress, 55, Victoria-street, S.W., 550; G. J. Fenwick, banker, Newcastle, 1,000; executors of A. Field, 700; A. S. Stevenson, Tynemouth, 700; Right Hon. W. H. Smith, M.P., 3, Grosvenor place, S.W., 500; A. Morrison, 53, Coleman-street, E.C., 2,000; J. Dilks, Nottingham, 500; London Trust Company, Limited, 500; F. R. Leyland, 49, Prince's Gate, S.W., 3,319; H. S. Cole, Blenheim Lodge, Sutton, S.W. 1956; S. E. Phillips, Shooter's Hill, 800; J. Balfour, 14, King's Arms Yard, E.C., 2,502; R. Paull, 1,100, and D. Mackinnon, 1,250, 13, Austin Friars, E.C.; W. C. Quilter, M.P., 14, King's Arms Yard, E.C., 5,044; H. C. Donovan, Middleton House, Westcombe Park, S.E., 670; H. L. Bischoffshein, 31, Throgmorton-street, E.C., 550; G. M. Davey, 20, Essex-street, W.C., 550; C. Morrison, 53, Coleman-street, E.C., 758; Viscount de Stern, 10, Great Stanhope-street, W., 2,500; B. Pell 6, Granville Park, Blackheath 1,000. The principal holders of the fully-paid shares are S. White, Temple-street, Liverpool, 6,900; J. W. Swan, Lauriston, Bromley, Kent, 2,625; S. White and J. C. Swan, of 1, Dean-street, Newcastle, 1,400; and F. R. Leyland, 1,725.

THETFORD ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The first return of this Company, made up to November 30, 1891, was filed on December 14, 1891. The Company was registered on June 23, 1890, with a nominal capital of £5,000 in £10 shares. 368 shares have been taken up, upon each of which £6 has been called and paid, with the exception of £3. The principal shareholders are Mr. W. Jackson, of Knottingley, Yorks, and Messrs. Charles Burrell and Sons (Limited), of Thetford, Norfolk, each of whom hold 175 shares. Registered office: St. Nicholas-street, Thetford, Norfolk.

WOODHOUSE AND RAWSON UNITED (LIMITED).—The annual return of this Company, made up to November 27, 1891, was filed on the 17th of the following month. The Company was registered on July 12, 1889, with a capital of £350,000, in £5 shares, to unite the businesses of (1) Woodhouse and Rawson (Limited), (2) Woodhouse and Rawson Electric Supply Company of Great Britain (Limited), (3) Woodhouse and Rawson Electric Manufacturing Company (Limited), (4) Woodhouse and Rawson Electric Contract and Maintenance Company (Limited), and (5) C. L. Baker and Company (Limited). On the 12th February last the capital was increased to £350,000, making 60,000 ordinary and 50,000 preference shares of £5 each. Of these, 55,170 ordinary and 41,118 preference shares have been taken up, of which 8,564 ordinary and 9,936 preference shares (a total of 18,500) were issued as fully paid. On 34,107 shares £5 per share has been called; on 5,281, £1 per share; on 4,045, £2 per share; and on 34,355. £2 10s. per share has been called, resulting in a payment of £268,163 10s. (including calls in advance), leaving £1,630 in arrears. £92,500 is considered as fully paid, and £11 10s. has been paid on 3 ordinary and 20 preference shares which have been forfeited. Registered office: 88, Queen Victoria-street, E.C.

CITY NOTES, &c.

AFRICAN DIRECT TELEGRAPH COMPANY (LIMITED). — Notice is given in our advertisement columns that the coupons on this Company's Four per Cent. Mortgage Debentures to bearer, due January 1st next, will be paid on and after that date, at the Alliance Bank, Bartholomew-lane, London, E.C. Coupons must be left at the Alliance Bank three clear days for examination.

pany's Second Issue of Five per Cent. Debentures, due 31st inst., will be paid on and after that date at the Alliance Bank, Bartholomew-lane, London, E.C. Coupons must be left at the Alliance Bank three clear days for examination.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts of this Company for the week ended December 20th amounted to £788; aggregate receipts for half-year to date, £18,356.

ELECTRIC CONSTRUCTION CORPORATION (LIMITED).—Application has been made to the Stock Exchange Committee to allow the vendors' shares Nos. 45,101 to 50,000 of this Corporation to be quoted in the official list.

METROPOLITAN ELECTRIC SUPPLY COMPANY (LIMITED).—The Stock Exchange Committee have ordered the vendors' shares Nos. 101 to 2,132, and additional shares Nos. 2,133 to 6,100 to be quoted in the official list.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the half-month to December 15th were £2,514 as compared with £2,559 in the corresponding period of last year, showing a decrease of £45.

FOOTBALL.—SILVERTOWN STAFF v. SIEMENS BROS.—This match was played last Saturday at Charlton before an enthusiastic body of spectators, and resulted in a win for Silvertown by one goal three tries to nil. Tries by Cardell (2), Lumsden, and Daubeny, one of which was neatly converted by P. Evans. The first half of the game was of a fairly even character, but in the latter half Silvertown had matters more in their own hands. Referee, H. Tuson, Wickham Park. Touch judges, W. E. Gray and S. Russell. In the evening both teams, by the kind invitation of Mr. W. E. Gray, dined at the Holborn Restaurant.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 711.—Vol. XXVIII. FRIDAY, JANUARY 1, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

A large proportion of the information contained in the statistical pages of our present issue has been afforded to us by the secretaries of the different companies. But there is a limit to the number of questions which these busy men will answer, and many of the figures have been filled in by careful searching through our back numbers. In some cases we have been obliged to leave blanks. The Notting Hill Company, for example, cannot tell us the present capacity of their plant nor the ultimate capacity of their station. Without troubling the companies for figures, which can be arrived at with a revised map of the districts and a planimeter, we have obtained the number of square miles of the different districts which are allotted to the London supply companies. But some of these have large slices of the parks, and those which border on the river trace their boundary along mid-stream. We therefore give a second set of figures for the net area over which lighting may be done, and from these we get the plant capacity in lamps per square mile, which is a measure of the value of the district. The area of St. Pancras is about 4·1 square miles, but so much of the northern part is park and common land that it is impossible to define the portion available for lighting. These figures do not relate to the number of lamps connected, but to the possible output of the present plant.

London Statutory Supply Companies' Districts in order of net area in square miles, exclusive of parks, &c.

	Gross.	Net.
Metropolitan	5·45	4·6
London	4·29	3·37
Westminster	2·56	1·9
Chelsea	1·23	1·13
House-to-House	0·94	0·77
Notting Hill	0·81	0·69
Kensington and Knightsbridge	0·97	0·67
St. James and Pall Mall	0·24	0·24
Electricity Supply	0·43	0·18

Supply Companies in order of plant capacity in lamps.

Westminster	137,000
Metropolitan	95,000
London	90,000
Kensington	50,000
St. James	40,000
Electricity Supply	38,000
Chelsea	30,000
House-to-House	25,000

Supply Companies in order of plant capacity in lamps per square mile (net, exclusive of parks).

St. James	167,000
Kensington	74,600
Westminster	72,100
House-to-House	32,400
London	26,700
Chelsea	26,600
Electricity Supply	21,000
Metropolitan	20,600

The progress of electric lighting in London in 1891 has taken place rather in the number of fresh houses which have been coupled to the supply mains than in the additional streets in which fresh mains have been laid. While there has been a very large increase in the number of lamps attached to the supply company's systems, the additional length of streets, as shown in our map, which is now in an advanced stage of preparation, is remarkably small. On comparing this map with the one we published at the commencement of last year, it will be found that the increase in the streets in some districts is quite insignificant. The Belgravia district of the Westminster Company shows but little alteration, although a very large increase has taken place in the actual number of lamps. The Mayfair and Grosvenor-square district is now thickly covered, and in almost every yard there is fierce competition with the London Electric Supply Corporation. The most notable example of fresh ground covered is the extension of the Metropolitan Company in the Bayswater district. Our map, which we hope to publish on the 15th inst., will show no less than four companies in Coventry-street, which is the boundary of the St. James, Metropolitan, and the Electricity Supply Corporation, and which runs through the extensive district allotted to the London Electric Supply Corporation.

The spread of electric lighting in the residential districts is largely impeded by the uncertain and short tenure of house property. During 1889 about one hundred miles of mains were laid in front of the best houses, and a large number of these availed themselves immediately of the supply, but out of every hundred houses in front of which mains have been laid for a twelvemonth, and which are not yet wired, ninety are likely to remain so until the termination of their present leases. Tenants are reluctant to wire their houses when a comparatively short portion of the lease remains, unless an

Digitized by Google

arrangement can be made with the landlord; and, as a matter of fact, there is great difficulty in making such an arrangement. New houses are sure to be wired by the builders if the mains are at hand, and the Chelsea Company has benefited largely by the building operations on the Cadogan estate. It is difficult to see how supply companies can encourage the wiring of houses, as, although a tenant may be willing to pay for the wiring by instalments, should he leave the house; the supply company have no claim whatever upon the incoming tenant, whilst under the terms of the Act he can demand a supply of current. If it could be arranged that the Company could sue him for the use of the wires, this difficulty might be met; but these unfortunately become landlord's fixtures, and the supply companies would be driven to make the best terms they could with the landlord. The majority of landlords are content to keep their houses in a barely tenantable condition; the bursting of water-pipes is frequently treated as reasonable wear and tear to be repaired by the tenant, and electric lighting becomes to be regarded as a mere luxury.

The recent agitation at Cambridge on the subject of "compulsory Greek" threatened at one time to raise an estrangement between men of science and men of letters; but happily so many well-known representatives of the former class threw their influence into that side which may be said to be both liberal and conservative, that this danger was averted. Proving conclusively that much as a thorough education is to be insisted on, and that the University is by no means opposed to the recognition of science, the Senate passed last week, without any opposition, two "graces," one with the view of promoting the development of an Engineering School in the University, and the other to take into consideration the establishment of an honours degree in Mechanical Science. While wishing Prof. Ewing every success in developing the teaching of engineering at Cambridge, we cannot help thinking that the step which the University has taken is more remarkable than a concession on the Greek question. We do not allude to the development of the Engineering School; for the University might encourage the study of farming, navigation, or even financial science; but the establishment of a Tripos, and the granting of an honours degree places not only Mechanical Science but the functions of the University in a new light. The advancement of learning and the continually increasing high pressure and competition of modern life must have its effects on the old Universities as well as on society at large; and while we should greatly regret to see a lessening of the important characteristics which distinguish these bodies from the younger establishments and technical colleges, the object is in this case so excellent that our conservative feelings give way.

The University of Cambridge has granted honour degrees in the Law Tripos for many years; but a graduate in this school is not fitted for an immediate appearance at the bar. And in an excellent leader in *The Times* of Christmas Day, making an appeal for benefaction wherewith to equip a laboratory, it is carefully pointed out that the new Tripos is not intended to supersede practical training. Dr. Fleming followed up this article with a plea for University College, and Mr. Capper for King's College. It is impossible to conceive the extent and direction in which that still immature branch of knowledge called Mechanical Science may develope in a well-equipped laboratory, with not too many students, a few good demonstrators, and an able professor not too much occupied with consulting work.

In no other branch of knowledge have analogies been more extensively used and more actively pushed than in electrical science. They have served a most useful purpose, but we cannot accept them as the premises of a logical conclusion. The comparison made between the three forms of energy present in heat, water-power, and electricity, which will be found in our correspondence columns, is delightfully simple, but fails to convince us. It is asked whether the third resembles the first or the second. Heat *is* energy; but in water-power the product of pounds of water into feet-fall is energy; and in electricity the product of amperes into volts is energy. The resemblance is little else than an accidental one, viz., that the second and third are composed of factors. But the factors are not homologous, and some have been suppressed. Though heat is in itself energy, there must be a difference of temperature or thermo-motive force before we can get work from it; and with water-power we must have gravitation or ponderomotive force before we can get energy. When we say that the product of pounds of water into feet-fall (i.e., foot-pounds) is energy, the "pounds" do not really denote the quantity of water, but the force of gravitation, which is conveniently measured in pounds. It is not, therefore, justifiable to compare the pounds of water—meaning a quantity of water—with coulombs, meaning a quantity of electricity.

We venture to differ with our valued correspondent as to the analogue of the turnstile. In the sentence which he quotes from our leader we implied that there are two distinct ways of measuring a crowd. A turnstile measures them as a current of persons, and, as our correspondent points out, this process may be repeated indefinitely. But we alluded to another way, viz., the collection and counting of the persons not as a current, but as a "static" quantity, and we can find no corresponding mode of measuring electricity unless as the charge in a condenser. But in this case we can easily recognise that the charge may be accounted for by a displacement strain of the ether; no idea of a concrete or material substance is needed. To the question, "Is it matter or is it motion?" we would reply by another question: "What is it that drives the wheels of a watch?" The spring alone will not do it, and the motion of the spring is an effect, not a cause. The proximate cause is the resilience of the spring when strained. We do not need the idea of horology to express the going of a watch, and we can similarly dispense with the idea of electricity. Electricity is not ether in the same way that sound is not air, and horology is not a steel spring.

The single objection which may be raised to the new expression "hindrance," which Mr. Heaviside advocates in our correspondence columns, is that it is not self-explana-

Digitized by Google

tory, and a distinct effort of memory is required to connect it with the physical quantity to which it is proposed to attach it, but which it cannot be said to designate or connote. Hindrance is no more explicit than obstruction, restraint, restriction, and has only the merit of being purer English. Mr. Heaviside is fond of coining words like conductance and permittance; and the advantage of these over a dictionary word like hindrance is that the man who coins them has a right to attach them to the idea which they are intended to designate. It is doubtful whether anyone has a right to apply the common word hindrance to the quantity known as L. The word chokage might be suggested as denoting something that is characteristic of a choking coil. To recollect the difference between chokage and impedance it should be remembered that impedance is a word savouring of theory, and that theorists are fond of periodic currents; while a choking coil being an ordinary sort of thing, chokage is applicable to intermittent, transient, and miscellaneous currents.

The Weston voltmeter came in for some high praise at a recent meeting of the Institution of Electrical Engineers, and we have heard it spoken of in the highest terms by people who knew what they were talking about, but who, being interested in the manufacture of electrical instruments, naturally do not care to publish their views. The average electrical engineer, it is to be regretted, is not very familiar with the "points" of a voltmeter; he swears at it, or at the maker, when he finds, always too late, that it has been misleading him; but he too often either knocks it about as he would a lineman's detector, or screws it on a switch-board within a few inches of a main cable. We should hesitate to publish the account of the remarkable experiment which is recorded in another column had not we already heard it described by an eye-witness. Prof. Silvanus Thompson says that English manufacturers know nothing about magnet making, Mr. Preece says that the magnets used by the Post Office are hard to beat; and somebody gets up every now and then with a phenomenal specimen at which everyone who believes him is surprised, but none of whom ever think of sending any orders. The strength and permanence of the magnet in the Weston instrument are its leading features. We hear different accounts about the necessity for occasional recalibration, but are inclined to think that if it were not for a very slender and weak aluminium pointer it would compare well with the best English instruments.

An action which is now pending in the Dundee Small Debts Court is of no little interest to telephone subscribers at large. The National Company is suing a local firm for the amount of their telephone rental, payable in advance, for the period November 1891-92. The defence put in is that any contract which may have been entered into has been voided by reason of the bad telephone service. It is something new to hear of a plea of this kind north of the Tweed, where we are always being told things telephonic are as they should be. If this ingenious defence proves successful, what a terrible instrument of energetic protest lies ready to hand for those London subscribers who are not yet satisfied.

The Elmore Companies do not often come in for kind words. And we were not surprised to hear some scoffing at the wire manufacturing company which has no intention of manufacturing wire, and which pays £5,000 royalty in advance for the right to split up tubes and sell them as sheets. But at the meeting of this Company, which is reported in another column, an announcement was made of an interesting modification of the Elmore process. The tube as it grows is repeatedly exposed to the air, and at each exposure a slight oxidation takes place, sufficiently thin to allow of further deposition, but thick enough to prevent adherence. The resulting tube, being ripped up and flattened, is transformed into "a number of beautifully burnished sheets of perfectly even surface and thickness, and equal in every way to those known to the trade as planished sheet." This is undoubtedly interesting and pretty. Whether it has any more commercial value than other Elmore products we really do not know, and shrink from inquiring.

Obituary.—The death is announced, at the age of seventy of the eminent chemist, Prof. Stas.

Manchester.—It is hoped that in about a month a start will be made with the works connected with the installation of the electric light, which includes the lighting of the Town Hall.

Telegraphic Communication with South Africa. — The Eastern and South African Telegraph Company notifies the restoration of its Aden-Zanzibar cable, thus re-establishing telegraphic communication with South Africa by the East Coast. Both the East and West Coast routes are now in working order.

Camera Club.— We are requested to state that the eighth of the series of One Man Photographic Exhibitions at the Camera Club will be open on and after Tuesday next, from 10 a.m. to 4 p.m., on presentation of cards, which can be obtained from members, or from the Hon. Secretary. The pictures will be on view for about six weeks.

Bristol.—At the meeting of the Town Council last week, it was considered advisable, on the report of Mr. Preece, to pile the whole of the ground, in order to ensure the stability of the central station. The Lancashire boiler, as more suitable for the Bristol water and the local coal, has also been adopted, in place of the one originally recommended.

Featherstone.—At a recent meeting of the Local Board a letter was read from Lord Masham, offering to light up North Featherstone for a term of 15 to 20 years with the electric light for the sum of £20 per year and 4d. per hour during the time the current was used. A resolution accepting the offer was carried. At present the district is lighted by oil-lamps.

City and South London Railway.—The Directors of the City and South London Railway have made a further increase in their fares. The fares from the Oval to any of the intermediate stations are now raised to 2½d. between the hours of 8 a.m. and 10 a.m. This alteration is said to be because of the great traffic at this station, especially when any sports are going on at the Oval.

Personal.—We are informed that from to-day Mr. H. Graham Harris—who has for so many years been principal assistant—will become Sir Frederick Bramwell's partner, and that the business heretofore practised by him at 5, Great George-street will be continued under the style of "Bramwell and Harris," to whom it is requested all letters on matters of business should be addressed.

The Association for the Improvement of Geometrical Teaching.—We call the attention of those of our readers who are interested in the objects of this Association to the fact that a meeting will be held on Saturday, the 16th inst., at University College, Gower-street. The afternoon sitting will commence at 2 p.m., and several Papers will be read, which will be announced in due course in our Societies' Meetings columns.

Crystal Palace Electrical Exhibition. — It is officially announced that this Exhibition will be formally opened on January 9, 1892. Considerable progress has been made with many of the exhibits, some of which are of considerable magnitude, and it has been found that it would be impossible to have these all in position by January 1st, as was originally intended. We have been favoured with a lengthy list of exhibitors, together with the numbers and positions of their stands.

"Electrical Plant."—Mr. E. R. Dolby informs us that he retires from the editorship of *Electrical Plant* after editing the Special Central Station Number and the ordinary January issue, 1892, and that he will devote his entire attention to his consulting practice at 8, Princes-street, Westminster. Mr. H. Cuthbert Hall, who has acted as Mr. Dolby's assistant for the special number, will undertake the editorship, and the offices of the journal will be at 52, Queen Victoria-street, E.C.

"L'Électricien."—Our Paris contemporary, *L'Electricien*, announces that from to-day it will be under the management of an editorial committee consisting of Prof. Monnier (École Centrale des Arts et Manufactures), Prof. Éric Gérard (Institut Électrotechnique Montefiore), M. Félix Lucas, M. Emile Dieudonné, M. Eugène Meylan, M. Montpellier (founder of the *Révue Internationale de l'Electricité*). The chief object of the appointment of a committee is to secure absolute impartiality.

Liverpool.—The Watch Committee have adopted a resolution that the Town Clerk inform the Board of Trade that the Council object to the Provisional Order applied for by the Liverpool Electric Supply Company; and also that the consideration of the memorial signed by consumers of electricity in Liverpool, requesting the Corporation to give their consent to the application of the Liverpool Electric Supply Company, for a Provisional Order, be postponed until the second meeting in January.

The Glasgow Corporation and Messrs. Muir, Mavor, and Coulson.—After much negotiation, it has now practically been resolved by the Electric Lighting Committee of the Corporation to take over the business and plant of Messrs. Muir, Mavor, and Coulson, who have certainly been the pioneers of central-station electric lighting in Glasgow. At first the lighting was conducted from a low-tension station in Miller-street, chiefly to carry out a contract for the General Post Office in George-square, about 200 or 300 yards distant. In course of time the demand for electric lighting in silversmiths' shops, warehouses, &c., in the centre of the city became so great that Messrs. Muir, Mavor and Coulson were induced to start another central station on the alternate-current transformer system. The number of consumers has gone on increasing until the generating machinery is unequal to the demands made upon it. At the request of the Lighting Committee of the Corporation, Messrs. Muir, Mavor and Coulson stated the terms on which they were willing to make over to the city their property and entire interests as suppliers of electric light from their two central stations, and the sum of £30,000 was named as the amount wanted. Further, they placed their books and balance-sheets for three years at the service of the Committee of the Town Council, the convener of which, acting under the powers given to him, appointed a local accountant to report upon the firm's business and property, as shown by the books and balance-sheets. He also appointed an electrical expert to assist the accountant in making out a correct valuation. The valuation arrived at in this way was under £14,000. Finally, the Committee received a formal offer from the Company to dispose of their whole undertaking for the amount of £15,000. Of course, the terms of the proposed bargain have to be approved of by the Town Council before they become binding, but there is every probability that the whole undertaking will formally pass into the hands of the Corporation by March 1st, 1892.

The Proposed Electric Railways in the Metropolis.—The following additional particulars with regard to the various tubular electric railways, for which it is proposed to obtain powers next Session, may be of some interest:—The Waterloo-City (Mansion House) Railway, which will be 1 mile 4 furlongs 6·8 chains long, is fathered by Sir John B. Simeon, Lieut.-Colonel H. W. Campbell, Major-General Taylor Du Plat, Mr. E. A. Guest, and Mr. Wyndham S. Portal. The proposed capital is £540,000, with borrowing powers up to £180,000. The time for completing the line is, as in all the other cases, five years. The Waterloo-Baker-street (Dorset-square) Railway is fathered by Lieut.-Colonel H. W. Campbell, Major-General Taylor Du Plat, Colonel A. H. Bircham, Lieutenant-Colonel F. D. Gray, and Mr. A. R. Ricardo. A capital of £1,250,000 is proposed. The Finsbury Park (Great Northern Railway) City (Finsbury-pavement) Railway, which is promoted by the Great Northern Railway Company will have a capital of £1,500,000, in shares of £10 each, and the works which it is proposed to execute are (1) a railway 5 furlongs 5·70 chains in length in the parish of St. Mary, Islington, commencing by a junction with the up line of the Finsbury Park and Canonbury branch of the Great Northern Railway and terminating at Drayton-park, Holloway; (2) a railway 1 furlong 1 chain in length, commencing by a junction with the down line of the Great Northern Railway, and terminating at the same point as railway No. 1; (3) a railway 2 miles 5 furlongs 1·4 chains in length, commencing by a junction with the terminus of Nos. 1 and 2 railways, and terminating in the parish of St. Stephen, Coleman-street, at Finsbury-pavement, opposite the north side of West-street. The Hampstead-St Pancras-Charing Cross line does not appear to have got to the Bill stage. Finally, we have two extensions, viz, the Northern prolongation of the City and South London Railway to the Angel, Islington (2 miles 5 furlongs 3 chains), for which some £810,000 will be wanted, with borrowing powers up to £270,000; and the eastward prolongation of the Central London Railway from the Mansion House to Liverpool Street Station, for which £150,000, with borrowing powers up to £50,000, is scheduled.

Telegraphic Communication with Rock Lighthouses and with Lightships.—In a letter to *The Times* of Wednesday, Mr. R. S. Culley sums up the difficulties, frequently alluded to in these columns, which beset the maintenance of telegraphic connections with lightships or with isolated lighthouses. The difficulties are, he says, as follows:—"The lighthouses are exposed to the full force of the waves, which at times run up even to the tops of the towers. The rocks are rough and the sea bottom rough also, so that the position is about the worst possible for a cable, which would be rubbed to and fro and ground against the hard stone, and would, therefore, have to be made very heavy and strong to secure even a short life. Repairs would be difficult. It is possible to repair a cable in the open sea in a favourable situation only in tolerably calm weather. It would require calmer weather still in such a situation. The repairing vessel would have to wait in the nearest available anchorage until a fine day with calm sea occurred, and if such a chance were lost it might be weeks before another day suited. We not infrequently hear that commuication of any sort with a lighthouse has been impracticable during many weeks. How much less then must be the chances of being able to lift and splice a heavy cable in deep water? Lightship difficulties are of a quite different nature; they arise from the constant motion of the vessel and from its swinging with the change of direction of the tidal current four times a day. The ship shifts her position each change of tide, and at times makes a complete circle. These motions are allowed for by the way her moorings are arranged; but a similar arrangement is, to say the least, very difficult indeed for an electric cable."—Lord Salisbury, in reply to earnest representations made to him on the subject, has given an assurance that should the members of Parliament, who for years past have asked for the appointment of a Select Committee to inquire into the subject of electrical communication between the shore and lighthouses, renew their request during the ensuing Session, the Government will offer no opposition to the proposal.

ELECTROMAGNETIC THEORY.—XXII.

BY OLIVER HEAVISIDE.

(*Continued from page 164.*)

§ 111. The auxiliary vectors just employed in the expansion of a vector into the sum of three vectors having any independent directions, are examples of vector products. Two vectors being given, their vector product is perpendicular to both of them. Of course, disregarding magnitude, there is but one such vector, viz., the normal to the plane containing the given vectors. Nor is the tensor of any consequence in the example in question, for it will be observed that one of the vectors, **l**, **m**, **n**, appears both in the numerator and in the denominator of one of the three fractions in equation (32), so that the values of the fractions are independent of the tensors of the auxiliary vectors.

But *the* vector product of two vectors has a strictly-fixed tensor, depending upon those of the component vectors and their inclination. There is particular advantage in taking the tensor of the vector product of **a** and **b** to be $ab \sin\theta$. Thus we *define* the vector product of two vectors **a** and **b** whose tensors are a and b, and whose included angle is θ, to be a third vector **c** whose tensor c equals $ab \sin\theta$, and whose direction is perpendicular to the plane of **a** and **b**; the positive direction of **c** being such that positive or right-handed rotation about **c** carries the vector **a** to **b**. This vector product is denoted by

$$\mathbf{c} = \mathbf{Vab}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (33)$$

and its tensor may be denoted by $\mathbf{V_0ab}$, so that we have

$$c = \mathbf{V_0ab} = ab \sin\theta \quad . \quad . \quad . \quad . \quad (34)$$

Similarly $\mathbf{V_1ab}$ may be used to denote the unit vector parallel to **Vab**.

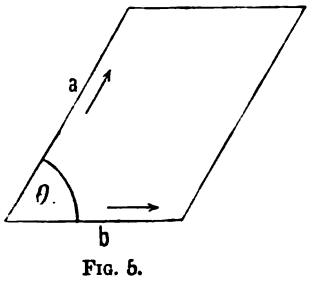

FIG. 5.

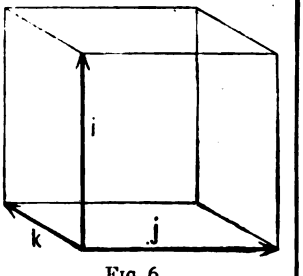

FIG. 6.

The only troublesome part is to correctly fix which way along the perpendicular to the plane of **a** and **b** is to be considered positive. Examples will serve to clinch the matter. Thus, let **a** be towards the north, and **b** towards the east on the earth's surface; then **c** is straight downwards. Again, in Fig. 5, the direction of **c** is downwards through the paper, and its tensor is the area of the parallelogram upon **a** and **b**.

Let **b** be fixed, whilst **a** moves round so as to vary the angle θ. Starting from coincidence, with $\theta = 0$, the tensor of **c** is zero. It reaches a maximum (downwards) when θ is a right angle, and falls to zero again when θ reaches two quadrants, and **a** is in the same line with **b**, though discurrent. After this, in the next two quadrants, the same numerical changes are gone through; but now, the sine being negative, **c** must be upwards from the paper.

The unit reference vectors **i**, **j**, **k** are so arranged that when, in (33), **a** is **i** and **b** is **j**, then **c** is **k**; noting in Fig. 6, that **k** is supposed to go downwards, or away from the reader. Thus, in accordance with our definition we have

$$\mathbf{Vij} = \mathbf{k}, \qquad \mathbf{Vjk} = \mathbf{i}, \qquad \mathbf{Vki} = \mathbf{j}, \quad . \quad . \quad (35)$$

because the mutual angles are quadrants and the tensors unity. Observe the preservation of the cyclical order **i**, **j**, **k** in (35). Also, we have

$$\mathbf{Vii} = 0, \qquad \mathbf{Vjj} = 0, \qquad \mathbf{Vkk} = 0, \quad . \quad . \quad (36)$$

because the vectors paired are coincident.

By the definition the reversal of the order of the letters in a vector product negatives it. Thus

$$\mathbf{Vab} = -\mathbf{Vba}. \quad . \quad . \quad . \quad . \quad . \quad (37)$$

Since the tensor of **Vab** is $ab \sin\theta$ and the scalar product **ab** is $ab \cos\theta$, we have

$$(\mathbf{ab})^2 + (\mathbf{Vab})^2 = (ab)^2. \quad . \quad . \quad . \quad . \quad (38)$$

§ 112. A vector product, being a vector, of course combines with other vectors to make scalar and vector products again. Thus **cVab**, where **c** is any new vector, means the scalar product of **c** and **Vab**; and **VcVab** means the vector product of **c** and **Vab**. These are both important combinations, which occur frequently, and their interpretations and expansions will be given presently. As illustrative of notation, it may be mentioned that $\mathbf{cV_0ab}$, where, as before explained, $\mathbf{V_0ab}$ is the tensor, is obviously a vector parallel to **c**, but $\mathbf{V_0ab}$ times as long. On the other hand, $\mathbf{cV_1ab}$, where $\mathbf{V_1ab}$ is the unit vector, is the same as $\mathbf{cVab}/\mathbf{V_0ab}$; since by dividing by the tensor we unitise the vector. Similarly as regards $\mathbf{VcV_1ab}$. We may also have $\mathbf{V_1cVab}$ and $\mathbf{V_1cV_1ab}$ and $\mathbf{V_0cVab}$, and various other modifications, whose meanings follow from the definition of a vector product and its notation.

We do not often go further in practical vector algebra than combinations in threes; for instance, on to **dVaVbc**, the scalar product of **d** and the previously explained **VaVbc**.

The scalar product **cVab** has an important geometrical illustration. Its value is given by

$$\mathbf{cVab} = \mathbf{V_0ab} \times c \cos\phi, \quad . \quad . \quad . \quad . \quad (39)$$

where ϕ is the angle between **c** and **Vab**. This is by the definition of the scalar product, and of the tensor of a vector.

Now refer to Fig. 5 again. We know that $\mathbf{V_0ab}$ is the area of the parallelogram. We also know that the volume of a parallelepiped is the product of its base and altitude. Construct, then, a parallelepiped whose three edges meeting at a corner are **a**, **b**, and **c**. The area of one of its bases is $\mathbf{V_0ab}$, and the corresponding altitude is $c \cos\phi$. Therefore, by (39), **cVab** is the volume of the parallelepiped.

But there are two other bases and two other altitudes to correspond, so there are two other ways of expressing the volume, giving the equalities

$$\mathbf{aVbc} = \mathbf{bVca} = \mathbf{cVab}, \quad . \quad . \quad . \quad . \quad (40)$$

in which observe the preservation of cyclical order, done to keep the sign the same throughout, as will be verified a little later.

§ 113. The semi-cartesian expansion of $\mathbf{c} = \mathbf{Vab}$ is

$$\mathbf{c} = \mathbf{i}(a_2b_3 - a_3b_2) + \mathbf{j}(a_3b_1 - a_1b_3) + \mathbf{k}(a_1b_2 - a_2b_1), \quad . \quad . \quad (41)$$

in terms of **i**, **j**, **k** and the scalar components of **a** and **b**.

To prove this, multiply (41) by **a** and **b** in turns to form the scalar products **ac** and **bc**. Do this by the rule embodied in equation (23). We get

$$\mathbf{ac} = a_1(a_2b_3 - a_3b_2) + a_2(a_3b_1 - a_1b_3) + a_3(a_1b_2 - a_2b_1),$$
$$\mathbf{bc} = b_1(a_2b_3 - a_3b_2) + b_1(a_3b_1 - a_1b_3) + b_3(a_1b_2 - a_2b_1).$$

But, by cancelling, all the terms on the right disappear. That is,

$$\mathbf{ac} = 0, \qquad \mathbf{bc} = 0.$$

From these we know that **c** is perpendicular to **a** and to **b**. It is, therefore, **Vab** itself, or a multiple of the same. To find its tensor, square (41). We get

$$c^2 = (a_2b_3 - a_3b_2)^2 + (a_3b_1 - a_1b_3)^2 + (a_1b_2 - a_2b_1)^2. \quad (42)$$

But this may, by common algebra, be transformed to

$$c^2 = (a_1^2 + a_2^2 + a_3^2)(b_1^2 + b_2^2 + b_3^2) - (a_1b_1 + a_2b_2 + a_3b_3)^2. \quad (43)$$

That is,

$$\mathbf{c}^2 = \mathbf{a}^2\mathbf{b}^2 - (\mathbf{ab})^2, \quad . \quad . \quad . \quad . \quad . \quad (44)$$

or,

$$c^2 = a^2b^2 - a^2b^2 \sin^2\theta = (ab \sin\theta)^2.$$

The tensor c is, therefore, that of **Vab** itself, or else its negative. Equation (44) is the same as (38), in a slightly different form. Equation (41) is proved, except that it remains to be seen whether the right member represents **Vab** or its negative.

To do this, we may remark that the angle between two planes is the same as the angle between the normals to the planes, if the normals coincide when the planes do, so that the three quantities in ( )'s in (41), which are the scalar projections of **c** on the axes, are also the areas of the projections

Digitized by Google

of the area $V_0\mathbf{ab}$ on the planes perpendicular to them. We have therefore only to verify that the projection of any plane on the plane normal to one of the axes is given correctly in sign by (41). Take a rectangle, parallel to the **j**, **k** plane, sides parallel to **j** and **k**, that is, $a_2\mathbf{j}$ and $b_3\mathbf{k}$; so that

$$\mathbf{c} = \mathbf{i}a_2b_3.$$

Here a_2b_3 is the projection of the rectangle on a parallel plane, and is correctly positive.

Now go back to (41). We have

$$\mathrm{V}\mathbf{ab} = \mathbf{i}(a_2b_3 - a_3b_2) + \dots \quad (45)$$

Similarly

$$\mathrm{V}\mathbf{ac} = \mathbf{i}(a_2c_3 - a_3c_2) + \dots \quad (46)$$

Add these together. We get

$$\mathrm{V}\mathbf{ab} + \mathrm{V}\mathbf{ac} = \mathbf{i}[a_2(b_3 + c_3) - a_3(b_2 + c_2)] + \dots \quad (47)$$

But the right member, by definition of a vector product, or by (41), means $\mathrm{V}\mathbf{a}(\mathbf{b}+\mathbf{c})$. That is,

$$\mathrm{V}\mathbf{a}(\mathbf{b}+\mathbf{c}) = \mathrm{V}\mathbf{ab} + \mathrm{V}\mathbf{ac}. \quad (48)$$

Similarly

$$\mathrm{V}\mathbf{d}(\mathbf{b}+\mathbf{c}) = \mathrm{V}\mathbf{db} + \mathrm{V}\mathbf{dc}. \quad (49)$$

So, by adding these again,

$$\mathrm{V}(\mathbf{a}+\mathbf{d})(\mathbf{b}+\mathbf{c}) = \mathrm{V}\mathbf{ab} + \mathrm{V}\mathbf{ac} + \mathrm{V}\mathbf{db} + \mathrm{V}\mathbf{dc}, \quad (50)$$

a very remarkable and important formula. It shows that the vector product of two vectors, **A** and **B**, equals the sum of all the vector products which can be made up out of the component vectors [$(\mathbf{a}+\mathbf{d})$ and $(\mathbf{b}+\mathbf{c})$ in (50)] into which we may divide **A** and **B**, provided we keep the components of **A** always before those of **B**. The necessity of this proviso of course follows from the reversal of $\mathrm{V}\mathbf{ab}$ with the order of **a** and **b**. Although (50) only shows this for two components to each primary vector, yet the process by which it was obtained evidently applies to any number of components.

Subject to the limitation named, the formula (50) is precisely similar to (17) § 108, relating to the scalar products. Now the truth of (17) could be seen without much trouble. A similar proof of (50), on the other hand, would not be at all easy to follow, owing to the many changes of direction involved in the vector products. This is why I have done it through **i**, **j**, **k**, which are auxiliaries of the greatest value. When in doubt and difficulty, fly to **i**, **j**, **k**.

On the other hand, although the establishment of (50) by geometry without algebra is difficult, and there is preliminary trouble in fixing the direction of a vector product, yet we see from (50) that vector products are nearly as easily to be manipulated algebraically as scalar products.

§ 114. By means of the formula (41) we can at once obtain the Cartesian expansion of the parallelepipedal $\mathbf{cVab}$. Use equation (23), applied to (41), remembering that **c** is now any vector, and we get

$$\mathbf{cVab} = c_1(a_2b_3 - a_3b_2) + c_2(a_3b_1 - a_1b_3) + c_3(a_1b_2 - a_2b_1). \quad (51)$$

By rearrangement of terms on the right side of this, putting the a's outside the brackets, we obtain $\mathbf{aVbc}$, and putting the b's outside, we obtain $\mathbf{bVca}$, and thus verify (40) again.

The vector $\mathrm{Vc}\mathrm{Vab}$ is, perhaps, most simply expanded through **i**, **j**, **k**. First write **d** for $\mathrm{V}\mathbf{ab}$, then by (41) we have

$$\mathrm{Vc}\mathbf{d} = \mathbf{i}(c_2d_3 - c_3d_2) + \dots .$$

Next put for d_1, d_2, d_3 their values in terms of a's and b's, given in (41), and we have

$$\mathrm{Vc}\mathrm{Vab} = \mathbf{i}[c_2(a_1b_2 - a_2b_1) - c_3(a_3b_1 - a_1b_3)] + \dots$$
$$= \mathbf{i}[a_1(b_2c_2 + b_3c_3) - b_1(a_2c_2 + a_3c_3)] + \dots$$

Lastly, add and subtract $a_1b_1c_1$, and we get

$$\mathrm{Vc}\mathrm{Vab} = \mathbf{i}[a_1\mathbf{bc} - b_1\mathbf{ac}] + \dots$$

Lastly, reconvert fully to vectors, and we have

$$\mathrm{Vc}\mathrm{Vab} = \mathbf{a}.\mathbf{bc} - \mathbf{b}.\mathbf{ca}. \quad (52)$$

This important formula should be remembered. That $\mathrm{Vc}\mathrm{Vab}$ is in the plane of **a** and **b** is evident beforehand, because $\mathrm{V}\mathbf{ab}$ is perpendicular to this plane, and multiplying by Vc sends it back into the plane. It is, therefore, expressible in terms of **a** and **b**, as in (52), which shows the magnitude of the components.

In some more complex formulæ it is sufficient to remember the principle upon which they are founded, as by its aid they can be recovered at any time. Thus in the case of

$$\mathbf{r} = f\mathbf{a} + g\mathbf{b} + h\mathbf{c}, \quad (53)$$

already treated, equation (31), if we use now $\mathrm{V}\mathbf{bc}$ for **l**, which was before any multiple of it, and similarly for **m** and **n**, we have

$$\mathbf{r} = \frac{\mathbf{r}\mathrm{V}\mathbf{bc}}{\mathbf{a}\mathrm{V}\mathbf{bc}}\mathbf{a} + \frac{\mathbf{r}\mathrm{V}\mathbf{ca}}{\mathbf{b}\mathrm{V}\mathbf{ca}}\mathbf{b} + \frac{\mathbf{r}\mathrm{V}\mathbf{ab}}{\mathbf{c}\mathrm{V}\mathbf{ab}}\mathbf{c}. \quad (54)$$

There is no occasion to put a formula like this in the memory, because it is so simply obtained at any time from (53) by multiplying by the auxiliary vectors so as to isolate f, g, h in turn and give their values.

Notice that the three denominators in (54) are equal. Also that by exchanging **a** and $\mathrm{V}\mathbf{bc}$, **b** and $\mathrm{V}\mathbf{ca}$, **c** and $\mathrm{V}\mathbf{ab}$, we obtain

$$\mathbf{r} = \frac{\mathbf{ra}}{\mathbf{a}\mathrm{V}\mathbf{bc}}\mathrm{V}\mathbf{bc} + \frac{\mathbf{rb}}{\mathbf{b}\mathrm{V}\mathbf{ca}}\mathrm{V}\mathbf{ca} + \frac{\mathbf{rc}}{\mathbf{c}\mathrm{V}\mathbf{ab}}\mathrm{V}\mathbf{ab}, \quad (55)$$

and this is also true, as we may at once prove by multiplying it in turns by **a**, **b**, and **c**, each of which operations nullifies two terms on the right. (55) is the expression of **r** in terms of three vectors, which are normal to the three planes of any three independent vectors, **a**, **b**, **c**, taken in pairs. Here, again, such a formula can be immediately recovered if wanted by attending to the principle concerned.

To obtain the cartesian expansion of any formula containing vectors is usually a quite mechanical operation. The cartesian, or semi-cartesian, representatives of a few fundamental functions being remembered, their substitution in the vector formula is all that is required. If the formula be scalar (although involving as many vectors as we please) the result is a single scalar formula in cartesians. But if it be a vector formula, it reduces to a semi-cartesian vector formula involving **i**, **j**, **k**, giving three scalar equations, one for each component.

The converse process, to put a scalar cartesian investigation into vectorial form, is less easy, though depending upon the same principles. Here the three component equations have to be reduced to one vector equation. It is very good practice to take a symmetrically written-out cartesian investigation and go through it, boiling it down to a vector investigation, using the unit reference vectors **i**, **j**, **k**, whenever found to be convenient.

(To be continued.)

ON THE CONSTRUCTION OF A BATTERY OF MINIATURE ACCUMULATORS.*

BY C. L. WEBER.

To charge electrometer needles, and for similar laboratory work, a Zamboni dry pile, or a battery of Voltaic cells, is usually employed. Such appliances, useful for static effects, are useless when a current is taken out of them. If miniature Planté accumulators are used their capacity is but small. For the calibration of torsion galvanometers, voltmeters, &c., and for measuring the insulation resistance of cables or electric light circuits a battery is often required which shall retain a constant E.M.F. of 100 volts, with an external resistance of 10,000 ohms; in other words, a battery is wanted which shall be able to yield a curreut of about 10 milliamperes. The author has recently constructed for the Munich testing laboratory, a battery capable of furnishing such a current for 36 hours.

The cells are made up in stout glass test tubes, 11 cms. high and 1·6 cm. in diameter. The spiral electrodes are formed of lead wire 1·5 m.m. in diameter and 50 cms. long. These spirals are arranged as shown in the figure, and are filled with active material. The leading-in wire of the lower electrode is protected by a piece of glass tubing. A paste composed of minium and sulphuric acid is put into the lower spiral, the upper one containing a litharge-sulphuric acid paste. The paste should be left to dry for about 24 hours before pouring in the electrolyte. The 60 cells of the battery were mounted in groups of 10 between two glass rods, supported at the ends by wooden uprights the tubes being kept vertical and separate by india-rubber bands. The whole battery can be enclosed in a box 29 × 16 × 18 cms.

This 60-cell battery is charged from the electric light mains in three parts, a liquid resistance of between 1,000 and 5,000 ohms

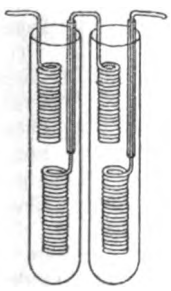
* Abstract from *La Lumiere Electrique*.

Digitized by Google

being interposed in the circuit, so that at the commencement the current is only 20 milliamperes; it is, however, gradually run up to 100 milliamperes, which is equivalent to about 30 milliamperes per group.

After having been formed and duly charged, the battery having been carried about and made considerable use of, was discharged for 36 hours through a resistance of 10,000 ohms. At the commencement of the test the terminal E.M.F. was 120 volts, and at the end of the test 100 volts.

The battery can easily furnish more powerful currents. Thus, in the above test the discharge current was at first 48 milliamperes, though at the end of seven hours it had fallen to 35 milliamperes. It has even been discharged at the rate of 65 milliamperes. The normal charge is 30 to 40 milliamperes for 20 hours. The loss of charge is small. At the end of a charge the E.M.F. was found to be 120 volts, and at the end of a week it was still 110 volts. This battery possesses a high capacity for its size, and may, therefore, prove of use for testing purposes.



Before finally settling on a definite mode of construction the author made a few experiments with regard to the disposition of the active material. He made up four groups, each of three cells, the lead spirals were all identical, but contained different quantities of active material. The four groups were all submitted to the same *régime*, and an initial current of 10 amperes being taken out of each set the time which this current took to fall 7 per cent. was noted :—

ELECTRIC LIGHTING NOTICES.

The following is a list, corrected up to date, of the Electric Lighting Notices for 1892. It will be seen that in all 17 Local Authorities and 25 Companies are applying for Provisional Orders; the grand total being 32, as against 70 for 1890. An asterisk denotes that the gas works are the property of the Local Authority.

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing, and Printing Offices:
SALISBURY COURT, FLEET ST., LONDON, E.C.
Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*" *All Editorial letters to be addressed to the Editor.*

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from Publishing Offices as above.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Old Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday.*

SMALL ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

SPECIAL NOTICE.—IN ACTIVE PREPARATION.

1891.

The twelve months that have elapsed since, in accordance with a useful and time-honoured custom, we last took a brief retrospective glance at the leading events in the electrical world, have been marked by a steady advance, not, however, without frequent breaks in the monotony which generally accompanies such a state of things. Electricity has been rightly dubbed the "Imperial Science;" and as this proud title is made good as much by the discovery and assimilation of new facts as by the forcible and sometimes premature annexation of branches of physical science hitherto free and independent, the events of 1891 will be found, like those of previous years, to have contributed several additional justifications for our claim to empire. Hertzian oscillations are now part of the stock in trade of that great and growing army of electro-technical students, the ranks of which become every day more hopelessly crowded; while EWING'S molecular theory of induced magnetism, by reason of its extreme plausibility and beautiful experimental analogue, has long been accepted as something axiomatic, and has been embodied in the latest edition of every respectable text-book. Electricity, from the pure science point of view, was therefore in some little danger of becoming dull, when it was announced to the scientific world, through the strange medium of *The Times*, that oxygen at −180°C. had been discovered by Prof. DEWAR to be highly magnetic. *A priori* this was to be expected; but an ocular demonstration of the correctness of our theoretical deductions is always a welcome event. Again, while the commonplace lamp maker was patiently awaiting the expiry of the Edison-Swan patents, and the central-station manager was speculating whether the market price of incandescent lamps would then be twelve or eighteen pence, Mr. NIKOLA TESLA, skating on the thin ice which in America so often separates pure research from commercial experimenting, gave us a tantalising glimpse of an ideal mode of illumination by means of bulbs devoid of filaments and made to glow by being placed in a rapidly-

Digitized by Google

alternating electrostatic field. At Cambridge, almost contemporaneously, Prof. J. J. THOMSON was upsetting all our preconceived notions as to the fitness of things by bringing out a transformer with no core and no copper, upon the practical possibilities of which, however, he, unlike his friendly competitor across the Atlantic, laid no stress whatever. In commercial electricity also, if we have not all become "drehstromers," the advent of the polyphase-current machine has shown us that the *ultima Thule* of dynamo design has not yet been reached, and that "extra high pressure" is not necessarily limited to 10,000 volts. The past year cannot, therefore, be added to the long list headed—devoid of interest.

This time last year it was by no means certain whether municipal electric lighting had come to stay; at the end of 1891 there is but little doubt that it will be a permanent feature in the municipal economy of the United Kingdom. It is indeed true that although nearly one hundred Orders have now been granted to Local Authorities, at the most only about a dozen of them can be said at present to be seriously taking the matter up; nevertheless, if we make allowance for the inertia inherent to the parochial mind, and remember the praiseworthy determination of many municipalities not to be rushed into taking a leap in the dark, it must be admitted that during the past twelve months municipal enterprise in this direction has not been backward. Early in the year the Dublin Corporation definitely plunged into electric lighting on the alternate-current transformer system, the scheme involving, as all municipal schemes should, a considerable amount of street lighting; the Dublin station is expected to get to work early this month. In Glasgow there has been a prolonged fight between the advocates of high and low pressure; and what with the gratuitous advice of a local evening newspaper on the one hand, and the more expensive counsel of Mr. R. E. CROMPTON, Prof. JAMIESON, and Sir WILLIAM THOMSON, on the other, the well-meaning ediles of that city have been completely befogged. In its hour of perplexity the municipality has sought the support of Prof. A. B. W. KENNEDY; and the able engineer to the Westminster Electric Supply Corporation will doubtless lull any qualms which the members of the Lighting Committee may have as to the suitability of the low-pressure system for supplying the needs of the industrial metropolis of Scotland. Bristol, with leisurely deliberation, proceeded some two years ago to take good advice on electric lighting matters; and on March 10th last £66,000 was voted towards a 10,000-light station on the alternate-current transformer system; street lighting to be represented by 100 arcs. The Bristol Electric Lighting Provisional Order was granted by the Board of Trade in 1888, yet at the end of 1891 the walls of the generating station were not above ground. At Cambridge, the question of municipal electric lighting, once on the verge of settlement, appears at the time of writing to have been, at any rate, temporarily shelved; the Local Government Board being strongly of opinion that drainage should precede electricity. Huddersfield has entered into a contract with the Brush Company for the erection of a central station, and both Manchester and Nottingham have decided to spend large sums on electric lighting. Nottingham is as yet committed to no definite scheme; but Cottonopolis is apparently ready to pin its faith on that complicated intricacy known as the five-wire system. During the autumn two municipal stations came into operation, namely, those of Brighton and St. Pancras, both on the low-pressure system. At Brighton electric lighting matters are a little out of joint, the original estimates have been exceeded, and the opposition is gathering strength. At St. Pancras all is reported to be as it should be. And here with mention of the fact that Portsmouth, Leicester, and several other towns are bestirring themselves, we must conclude the chronicle of municipal electric lighting in 1891. So far as contractors are concerned, the Local Authorities, it is clear, cannot be too energetic in undertaking their own electric lighting. But for the industry, as a whole, and looking into the future as well as at immediate advantages, it is as yet too early to assert that mere public spirit and the fear of the spasmodic tantrums of the ratepayer will conduce to as good results as the bracing atmosphere of healthy competition and the necessity of declaring a dividend. Everything that appertains to the health, safety, and public convenience of the community is undoubtedly within the scope of municipal enterprise, so that street lighting may well be undertaken by a Vestry or Town Council. No one proposes under ordinary circumstances to separate private and public lighting from each other, so we arrive by a process of ratiocination at the municipalisation of electricity.

To the central-station engineer the Metropolis has, as hitherto, been the principal focus of activity. No less than four stations have been added during the year to the list of those at work within the four-mile radius. In March the Westminster Electric Supply Corporation actively entered the field; and at the end of May the Notting Hill Company, on a less ambitious scale, followed suit. The total number of generating centres now in operation in London under statutory conditions is twenty, with a total capacity at the present moment of over 550,000 lights. A little more than twelve months ago Mr. FRANK BAILEY, of the Metropolitan Company, in a Paper read before the Society of Arts, gave the number of 8 c.p. lamps connected to the mains of the various London supply companies at 179,060. With the augmentation in plant and main capacity which has taken place during 1891, it will not, perhaps, be too hazardous to add about 50 per cent. to this figure, and to estimate the aggregate number of lamps now connected at 300,000 Our London central-station companies have not, however, been merely content to add to their capital outlay, but in one instance, at any rate, a substantial dividend has been declared. The decision of Mr. Justice KEKEWICH with regard to transformer sub-stations, to which we adverted last week, and the slow progress of the City lighting, to which general allusion has been made, need no more than a passing mention here.

In his Paper read before the Institution of Civil Engineers in April, Mr. CROMPTON set an example which it is, perhaps, not too much to expect will be more generally followed as time goes on. It is for the good of the lighting industry as a whole to bring down the price of the Board of Trade unit to the lowest figure compatible with an adequate return upon capital and an efficient service; and nothing would conduce more to the attainment of this object than a little less reticence on the part of our more prominent central-station managers. No one knows until he has tried what a mass of information useful to the electrical engineering community at large may be published in Papers or otherwise, without running any serious risk of "giving oneself away."

Electric traction still continues to make progress of that slow but sure description so dear to the English nation. The general adoption of electricity on urban tramways seems as far off as ever. At Leeds Mr. GRAFF BAKER has been plucky enough to give us a somewhat dubious blessing in the shape of a plain undiluted specimen of the American overhead trolley system. Mr. BAKER appears to have imported a consignment of his native characteristics, together with his cars, T.H. single-reduction motors, and other Yankee "notions;" for, despite the changed environment, he has already had a miniature

Digitized by Google

"smash," and is now "in interference" with the National Telephone Company. All who admire pluck will wish him well out of his difficulties. As to accumulator cars, it can only be said that they are still awaiting the perfect tramcar battery. The system is being tried on an important and practical scale at Birmingham, and, in spite of the very bad track on which the cars have been placed, the service is satisfactory, and the next statement of accounts will be looked for with interest. On the other hand, when we come to heavy work such as railways overhead or underground, or interurban tramways, the air is full of contracts concluded, or about to be concluded, and of projects to run steel tubes here, there, and everywhere. The Central London Railway scheme, which this summer met with the approval of the Upper House of the Legislature, has now reached the experimental borings stage, At Liverpool they have contracted with the Electric Construction Corporation to work their overhead railway at 3½d. per train mile (locomotive expenses); and on the South Staffordshire Tramways steam will e'er long give way to electricity. As to the tubular railways projected in London, they one and all meet decided wants. The City and South London Railway, when it has got its northern extension, will probably prove a more decided financial success; but it is to be hoped that before then a remedy will have been found for the mechanical or electrical defects which at present disturb the regularity of its train service and the equanimity of its patrons.

In the telephone world we have had a particularly eventful year. In February the Mutual Company commenced its attack on the telephonic monopoly by the opening of an exchange at Manchester. In March the laying of the St. Margaret's Bay-Sangatte cable, under exceptionally unfavourable meteorological conditions, was the last link in the telephonic chain connecting London with Paris. After the formal exchange of international courtesies customary on these occasions the wire was on the 1st of April thrown open to the public, who can now speak through to Paris for three minutes for the not exorbitant sum of eight shillings. The line has been extensively used, and, thanks to the care and skill of the Post Office officials on either side, speech is excellent. The success of this cable is very noteworthy, since it was designed on the strength of calculations, and in the full knowledge that these calculations are at variance with mathematical theory. The whole responsibility of the undertaking rested on Mr. Preece. No preliminary experiments were possible, since speech would be out of the question when the cable was coiled. It differs altogether in this respect, as a bold feat of electrical work, from the Lauffen-Frankfort transmission, or the thirty miles of Ferranti concentric mains. Had speech been difficult, no one but Mr. Preece would have been blamed, and we should have heard much about the heterodoxy of the K R. law. According to some official statistics just published there were 1,222 three-minute conversations in April, 1,491 in May, 1,709 in June, 1,988 in July, 2,276 in August, 2,811 in September, and 2,782 in October. The first seven months' working of the London-Paris telephone trunk line has thus resulted in 13,789 messages and in receipts amounting to £5,491. Into such favour has the service grown that the existing circuit is inadequate to the demands made upon it, and another will be brought in use as soon as possible. The chronic grumbling which the London telephone service evokes has been emphasised during 1891 by the formation of an association for the protection of telephone subscribers, by a remarkably significant warning from the late Postmaster-General, and by the threatened competition of the resuscitated New Telephone Company. Meanwhile the National Company continues to slowly but successfully improve its metropolitan system, and to absorb, in piecemeal fashion, the telephonic network of the country, its last willing victim being the not too prosperous South of England Telephone Company. The United States Patent Office, however, provided us with *the* event of the year, by issuing on November 17th last a patent applied for in June, 1877. Of the Berliner microphone patent, and all its history, our readers will by now have had enough. The most notable feature of the now uneventful history of submarine telegraphy was the all-round reduction in the Australasian cable rates on May day. In August our Continental cable system was added to by the laying of the Bacton-Emden cable, and many of the Submarine Cable Companies have added to their systems by the laying of additional lines. At home our land lines continue as of yore to be more and more used, but the rate of increase is steadily diminishing. The agitation for an organised system of telegraphic communication with our lighthouses and lightships gains continually in strength, and further inquiry into the matter has been practically promised.

Litigation, we are rejoiced to say, has not been particularly rife. The year began with the action brought by the British Tanning Company, owning the Worms and Balé electric tanning patents, against Mr. Groth; and we were treated to much instructive judicial argumentation on the nice question as to whether or not a pit with a framework of hides revolving within it is the mechanical equivalent of a revolving drum in which the hides are tumbled. Eventually it was decided that the Groth process did not infringe that of the British Tanning Company, and that moreover the Worms and Balé patent must be invalidated on a point of law. The effect of the latter part of the decision was, however, subsequently annulled by the passing of a special Act of Parliament rehabilitating the patent. In May the petition for the prolongation of the Jablochkoff distribution patent No. 1966 of 1877 was rejected, the strange discovery being made that one edition of the printed specification was dated differently on the face and on the cover. During the year the Lane-Fox distribution patent has been fitfully before the Courts; but up to now Mr. Lane-Fox has not been successful in bringing his adversaries to close quarters, although he has scored on several preliminary points, and managed to induce the St. James and Pall Mall Company to accept a licence from him as early as last January. In England, Mr. Brush's claim to be the inventor of compound winding is still being weighed in the scales of justice; in America, *per contra*, he has become the legal inventor of the Faure accumulator, and "thus the whirligig of time brings in his revenges."

The scientific societies, it is needless to say, have in 1891, as in previous years invited Papers, received Papers and had Papers thrust upon them. Whether the results are commensurate with the energy expended is open to question. The Civil and not the Electrical Engineers secured the two most practical Papers of the year, namely, that by Messrs. Ll. B. and C. Atkinson on "Electric Mining Machinery," and that by Mr. Crompton on "The Cost of the Generation and Distribution of Electrical Energy." At the Institution of Electrical Engineers Prof. Crookes began the year with a most brilliant Presidential address, and he was followed by Mr. Swinburne on "Transformer Distribution," Dr. Fleming on "Some Effects of Alternating Current Flow in Circuits having Capacity and Self-Induction," and Mr. Preece on "The Specification of Insulated Conductors for Electric Lighting and Other Purposes." During the discussion on Mr. Swinburne's Paper we heard for the first time of the alleged decrease in the iron losses of a transformer as the copper losses increased. This assertion gave rise to much contro-

Digitized by Google

versy, the last word of which has been Prof. Ewing's experiment, described in our issue of December 4th.

Among the events of the year we must not omit to mention the successful and instructive Electrical Exhibition on the Main; nor the striking and in many ways remarkable transmission from Lauffen on the Neckar to Frankfort. The Board of Trade Electrical Standards Committee, with its protracted deliberations, and epoch-marking decisions, deserves a place, and a very large one too, in the notes of any self-respecting chronicler. Major Cardew's humble underground laboratory has been busy with preliminary work, but is still waiting for its full equipment. The Faraday centenary celebrations at the Royal Institution in June were not less characteristic of the great man whom they commemorated, and of the country to which he belonged, than were the more boisterous celebrations in Germany which marked Helmholtz's seventieth birthday. Even a cursory annual review such as this would not be complete without some reference, however brief, to the losses which electrical science and industry have sustained during 1891. In May, Edmond Becquerel, a notable figure in the ranks of French *savants*, passed away. On the last day of the same month, David Brooks, better known, perhaps, in telegraph circles than to electric light engineers, died at Philadelphia. In June, Wilhelm Weber, the associate of Gauss, died at the ripe age of eighty-seven. In July, submarine telegraphy mourned the loss of Mr. Willoughby Smith; and by the death, in October, of the Abbé Jean Caselli land-line telegraphy lost an almost equally well-known pioneer; and to this list must be added the name of John Louis Crossley, of telephone transmitter fame, who died at Halifax at the end of August. "Years following years steal something every day; At last they steal us from ourselves away."

THE PRINCIPLES OF ALTERNATE CURRENT MEASUREMENT.

BY HUGH ERAT HARRISON, B.SC.

(*Continued from page 198.*)

Self-Induction.

Let P and Q (Fig. 8) represent two metal rings with a common axis. The ends of P are left open, but the ends of Q are connected with some source of current.

If a current C is sent round Q, lines of force will pass through it, many of which will also pass through P, all of them having emerged from the surface of the conductor Q.

Consider the line l_2 now passing through both rings; originally it was a little circle l_1, whose centre O was in the conductor, and its plane perpendicular to Q at O. This line increased in size until it developed into the line l_2, still a closed curve, but of such size that only a small portion of it can be shown in the figure. During its growth this line must have cut through P at some point O′, and the same applies to all the other lines, originally springing from points in Q, which now thread their way through both rings.

When a line of force cuts a conductor, it sets up, in that conductor, electromotive force; the line l_2, in cutting through O′, sets up an electromotive force at O′ downwards, and it will be found that all the lines set up E.M.F. in the same direction round P as they cut through it in turn. If an electrometer of sufficient delicacy were constructed and connected to the ends of P, an E.M.F. would be indicated all the time P is being cut, that is, all the time C is changing. The moment C becomes steady the lines of force cease to move, P is no longer being cut by them, and no matter how large C may be, no indication will be given by the electrometer.

When the current falls to zero the lines of force which always form closed curves collapse, fall back into Q, and in so doing cut through the various points in P again, but in the *reverse* direction, and the E.M.F. set up by this fresh cutting will also be *reversed*.

Suppose N to be the number of lines which pass through P when one ampere flows in Q, then N C lines pass through when C amperes flow. If the current took t seconds to rise from zero to C, the lines have cut P at an average rate of N C/t lines per second. If E is the average E.M.F. set up, then $E = 10^{-8} N C/t$.* During the next three seconds, suppose the current rises to C′; N C′ will be the total number of lines in P, that is, N (C′ − C) additional lines have cut in, and the average E.M.F. set up during the three seconds is $E = 10^{-8} N (C' - C)/3$.

It must be noted that the value of E has nothing whatever to do with the strength of the current, but is proportional to the *change of strength of current per second*.

If P has now a current sent through it while Q is connected with the electrometer, similar effects will, of course, be produced. A rising current in Q sets up an E.M.F. in the opposite direction in P, a falling current in Q sets up an E.M.F. in P in the same direction as that of the current; *mutatis mutandis*, the same happens as the current rises and falls in P.

Suppose the rings connected up (Fig. 9), so as to form a coil of two turns, the same current will pass through both. When the current rises the lines of force from Q which cut P, set up an E.M.F. in P which opposes the flow of the current in P, and at the same time the lines from P which cut through Q set up an E.M.F. opposing the flow of current in it also.

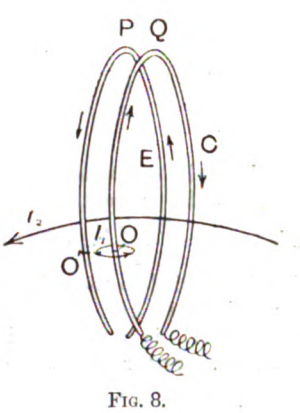

Fig. 8.

Fig. 9.

Indeed, the effect is the same as though a little local battery or dynamo machine were placed in each turn of the coil hindering a rising current, helping a falling current. This property, which a circuit possesses, of producing a local E.M.F. within itself when the current changes, is called "self-induction," and the coefficient of self-induction of a circuit is the value of the average E.M.F., measured in volts, set up when the current changes by one ampere in one second. The coefficient of self-induction is measured in secohms; the E.M.F. set up in a coil when the current changes at the rate of one ampere per second gives its coefficient of self-induction, measured in secohms.

This coefficient is a quantity easy to measure, but frequently next to impossible to calculate.

If the coil (Fig. 9) has n turns, each of these turns will be cut by the lines from $(n - 1)$ others, so that there will be nearly $(n - 1)$ times the original E.M.F. set up in each turn; and, as there are now n turns instead of 2, the E.M.F. will be roughly n^2 times as great as that previously set up in P or Q; hence, as the turns increase, the coefficient of self-induction increases with great rapidity.

With an unvarying current the effects of self-induction are *nil*; it is only since alternating currents have come into use for the distribution of electrical energy that the inductance of a coil may be of even more importance than its resistance.

Suppose a current is made to rise uniformly from zero to 4 amperes in a coil whose resistance is 2 ohms, during 8 seconds; to remain constant for a short period; and then to fall to zero at the same uniform rate. If time, current, and E.M.F. are represented in the same manner as in Fig. 3, the broken line

* The factor 10^{-8} has to be introduced owing to the numerical relations between the volt and ampere and the corresponding absolute units.

Digitized by Google

O A B D (Fig. 10) pictures the current, which does not vary during the interval of time $t_1 t_2$, and since by Ohm's law the E.M.F. driving a current is equal to the product of the value of the current into that of the resistance of the conductor, O A_1 B_1 D got by multiplying the ordinates of O A B D by 2, the resistance of the coils, gives the E.M.F. producing the current at each instant. If, however, the coil has a coefficient of self-induction of, say, 1·4 secohm, the E.M.F. O A_1 B_1 D is, while the current rises or falls, the resultant or algebraic sum of two electromotive forces, viz., the E.M.F. applied to the ends of the coil, and the local E.M.F. due to self-induction set up within the coil itself.

The rates at which the current rises and falls are At_1/Ot_1 and Bt_2/t_2D, both of which are equal to $4/8 = 0{\cdot}5$, so that the E.M.F. due to self-induction is in each case $1{\cdot}4 \times 0{\cdot}5 = 0{\cdot}7$. With a rising current this E.M.F. acts against it, and is, therefore, shown by a line F G parallel to and drawn at a distance 0·7 below O T, while H K, representing the E.M.F. due to self-induction, when the current falls, is a line parallel to O T but drawn 0·7 above it.

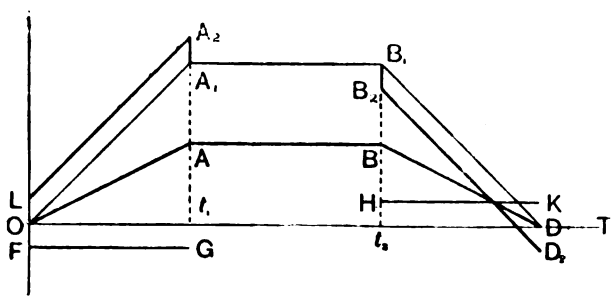

Fig. 10.

Let E = E.M.F. applied to the ends of the coil at any instant while the current is rising, and let C = the current flowing at the same instant; then by Ohm's law $C = \frac{E - 0{\cdot}7}{2}$, so that $E = 2C + 0{\cdot}7$, that is to say, the E.M.F. applied to the coil is 0·7 volt higher than that merely required to get the current through the resistance, and this E.M.F. is represented by the line L A_2, whose ordinates are 0·7 greater than those of OA_1.

Similarly the line B_2 D_2, whose ordinates are everywhere 0·7 less than those of B_1 D, pictures the E.M.F. applied to the bobbin when the current dies away, since the E.M.F. of self-induction acts with a falling current.

While, however, the current is unvarying, E = 2 C simply because self-induction does not come into play at all.

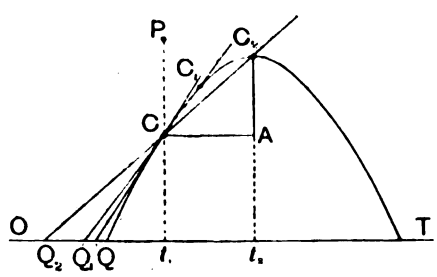

Fig. 11.

The application of the construction just given to the case of a current, whose *rate of variation* changes, is quite simple. Let Fig. 11 represent a single pulse of the alternating current previously referred to. Its value increases from t_1 C to $t_2 C_2$ that is by the amount A C_2 (if C A is drawn parallel to O T) during the time $t_1 t_2$, and its average rate of increase is $A C_2/t_1 t_2 = \frac{A C_2}{CA} = \tan C_2 Q_2 T$.

From the shape of the curve it is clear that the current increases less rapidly at C_2 than at C, and if a point C_1 nearer to C than C_2 be taken, the average rate of increase between the points C and C_1, that is, tan C_1 Q_1 T, approximates more closely to the rate of increase at C than the former value; finally, if a point so near to C as to be indistinguishable from it is taken, the line C Q becomes a tangent to the curve at C.

To find, therefore, the rate of change of the current at any instant, draw a tangent C Q to the curve at the point C under consideration, and note the tangent of the angle C Q T which this line makes with O T.

The value of the tangent of this angle can then be set off as the ordinate t_1P. In Fig. 12 the dotted line is the curve thus traced by a series of points P. This rate of variation curve, V, drawn for a sine curve, is itself a sine curve cutting

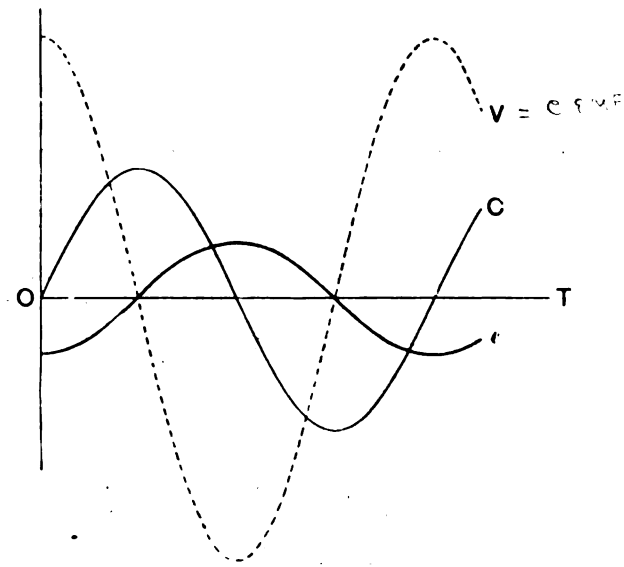

Fig. 12.

O T half way between the points where the current curve C cuts it. If the current is supposed to be flowing through a coil whose coefficient of self-induction is 0·25, multiplying the ordinates of the curve V by the coefficient of self-induction and reversing, the curve e is obtained showing the E.M.F. set up in the coil fron this cause.

Multiplying the ordinates of the current curve C (Fig. 13), by the resistance of the coil, the curve $\mathcal{E}$ is obtained showing the actual or resultant E.M.F. producing the current. If E is the E.M.F. between the terminals of the coil at each

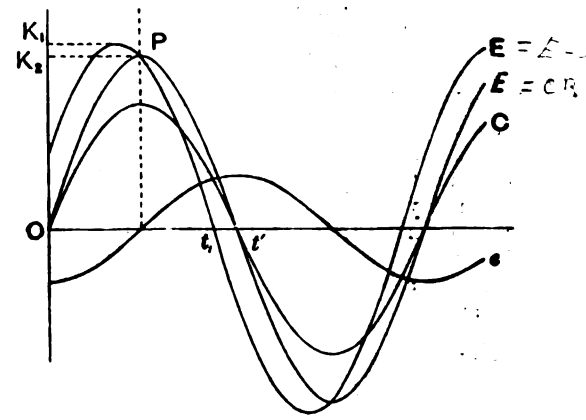

Fig. 13.

instant, $\mathcal{E} = E + e$, therefore, $E = \mathcal{E} - e$, and by subtracting the ordinates of e from those of $\mathcal{E}$ at each point, the curve E can be drawn.

E may be supposed to be the E.M.F. between the mains, proceeding from an alternating-current dynamo machine, across which the coil is connected. E will, therefore, be referred to as the E.M.F. in the mains.

The relative sizes of the curves in such a circuit can, of course, vary to almost any extent, but the relative positions are always the same. The relative positions of C, e, and $\mathcal{E}$, have already been explained; but it must now be noted that since when C, and therefore when $\mathcal{E}$ has its greatest value, $e = 0$, the curve E must always cut curve $\mathcal{E}$ at its highest point P.

The chief effects of self-induction in an alternating-current circuit are plainly shown in Fig. 13. The effect of self-induction is to reduce the E.M.F. producing the current in the ratio O K_2/O K_1, and the current is therefore reduced in like ratio.

Again, it will also be noticed that C has its greatest and least values at an interval of time, $t_1 t'$ later than the E.M.F. in the mains, and the current is therefore said to lag after this E.M.F.

Choking Coils.

The usual electromotive force provided by public supply companies on house mains is roughly 100 volts. If this voltage is too high for a lamp or other piece of apparatus through which one of their customers wishes to send a current, it can be reduced by placing a resistance coil in series with the apparatus in question.

To take an exceedingly simple case. Suppose a very large incandescent lamp, using 10 amperes and requiring 50 volts between its terminals, to be placed on a 100-volt circuit. If a coil of 5 ohms resistance is put in series with the lamp it will use up 50 volts. The number of watts used up by the combination is 10,000; of these 5,000 are usefully employed in incandescing the lamp, and 5,000 are uselessly employed in heating the resistance coil. Although no conductor has absolutely zero coefficient of self-induction, resistances may, nevertheless, be wound whose coefficient is negligible for most purposes. If this is the case in the present instance the coil may be used with equal effect for an unvarying or alternating current.

With an alternating current it has been shown (*see* Fig. 13) that a coil with self-induction reduces the effective E.M.F. by producing an E.M.F. differing in phase from that of the E.M.F. in the mains. The superfluous 50 volts can, therefore, also be got rid of by means of a coil with a suitable coefficient of self-induction. A coil used in this manner is called a *choking coil*. It is, of course, impossible to wind a coil with no resistance, but a choking coil can be wound whose resistance is small compared with that which the corresponding resistance coil would have. To simplify matters the resistance of the choking coil will consequently be neglected.

Suppose there are 100 complete vibrations of the E.M.F. per second; if the volt be taken as the unit of E.M.F., the second the unit of time, and the centimetre the unit of length; the E.M.F. curve for a half vibration would be about 150 centimetres high, standing on a base 0·005 centimetre long, that is, one whose height would be 30,000 times its width, a curve practically impossible to draw.

One way out of the difficulty would be to take ten volts as unit E.M.F. and say 0·001 second as unit of time. The curve would then be about 15cms. high and 5cms. wide, a fairly manageable size; and the required result being obtained from the curve, it could be multiplied by the necessary factor to get the real numbers.

Perhaps a simpler way still is to solve a problem similar to that about to be considered; assuming the maximum E.M.F. between the mains to be 10 and the number of complete vibrations to be 1 in 10 seconds, to find out how this E.M.F. can be reduced to a maximum of five at the lamp terminals, then to obtain, by simple arithmetic, the quantities required for the real lamp circuit.

Draw the curve E (Fig. 14), whose maximum height [E] equals 10, to represent the E.M.F. between the mains. This has to be reduced to one-half; draw, therefore, the line A B parallel to O T, where O A equals 5. It was shown in Fig. 13 that the resultant E.M.F. curve is cut at its highest point by curve E, which lags behind it; B is therefore the highest point of this curve, and it can now be drawn. As this curve has previously been got from the current curve by multiplying its ordinates into the resistance of the circuit, it may be called the C r curve where C is the current flowing and r the resistance of the lamp. The E.M.F. due to self-induction is greatest when C, and therefore C r, is zero; hence the top or bottom of the e curve occurs at the point of time t_1, where, the resultant E.M.F. being nothing, the E.M.F. of self-induction exactly balances that in the mains; hence, if t_1 D equals t_1 F, D is the lowest point on the e curve, which can now be drawn, cutting O T at t_2, where C r is a maximum.

If t_1 D is measured its length will be found to be 8·7 nearly. From this it appears that an alternating E.M.F., whose maximum value is 10, can be reduced to half by means of a choking coil that gives an E.M.F. of 8·7, when the current passing through it is varying most rapidly, that is, when its direction is reversing.

It is important to note that the number 8·7 is independent of both the current and the number of alternations per second.

It is now easy to find the coefficient of self-induction necessary for the case originally taken.

If the alternating E.M.F. measured on a balance is 100, the maximum height of the curve representing it would be found to be 141·4; but to make Fig. 14 of manageable size, the maximum E.M.F. between the mains and the lamp terminals were reduced to 10 and 5 volts respectively. To make the heights of the curves in Fig. 14 represent the true E.M.F., their ordinates would have to be multiplied by 14·14, making 8·7 × 14·14 = 123. The actual current taken by the lamp is 10, so that the maximum height of the current-curve would be 14·14.

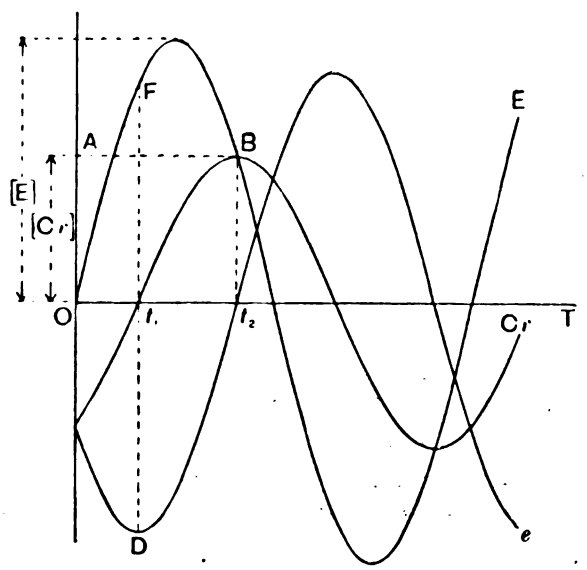

Fig. 14.

Now, a simple sine curve ($y = \sin x$) is 1cm. high and 3·14cms. wide, the angle at which it cuts the axis of x is 45deg., that is, its rate of increase is tan 45deg.; if the height of this simple curve is increased to 14·14, its rate of increase at the same point becomes 14·14 tan 45deg.; finally, if its width be diminished from 3·14 to ·005, the curve is now the required current-curve, and the rate of change as it crosses O T is 14·14 × 3·14/·005 tan 45deg. = 8886 nearly. If S equals the required coefficient of self-induction of the coil, 123 = S × 8886 ∴ S = 123/8886 = 0·0138.

The electromotive force between the mains could be reduced to 50 between the lamp terminals, either by the introduction, in series with the lamp, of a coil with no coefficient of self-induction and of 5 ohms resistance, or a coil with no resistance and a coefficient of self-induction of 0·0138 secohm.

(To be continued.)

THE WESTON DIRECT-READING ALTERNATING AND CONTINUOUS CURRENT VOLTMETER.*

Mr. Edward Weston several years ago invented a type of measuring instrument which embodied in its construction a permanent magnet and a movable coil, which moved in the gap included between the poles of the field-magnet and a soft-iron core. This combination formed practically a closed magnetic circuit, which experience has proved to be practically absolutely permanent in its nature. In proof of this we need only cite an experiment, which was as follows: A continuous-current voltmeter of the Weston type was attached to a circuit reading 100 volts, and by

* From the *Electrical Engineer* of New York.

Digitized by Google

bringing a magnet in contact with the poles of the magnet of the instrument itself, so that the N. and S. poles respectively came in contact, the reading of the instrument was changed from 100 to 22. The magnets were then struck repeated blows with a hammer in order to facilitate any change which might take place in the condition of the magnet of the instrument. The auxiliary magnet was then withdrawn, whereupon the needle resumed its original indication of 100 volts within one-tenth of a division, proving practically that no sensible change had taken place in the condition of the magnet.

The experiment was then tried of increasing the strength of the instrument magnet by placing the N. pole of the auxiliary magnet in contact with the N. pole of the instrument magnet, both S. poles also being in contact. The increase in the field thus brought about served to throw the index off the scale. The shocking of the magnets was then repeated, but, upon withdrawal of the disturbing magnet, the index resumed its first position within less than one-tenth of a division. A more crucial test could not be devised to show the permanency of the magnets employed by Mr. Weston in his well-known type of instrument. Indeed, Mr. Weston goes even so far as to place greater reliance in his instruments than in the tangent galvanometer.

With this success gained in the field of continuous-current instruments, Mr. Weston proposed to himself the problem of constructing an instrument of like accuracy and permanency which could be used equally well on circuits carrying either alternating or continuous currents. In casting about for the best principle upon which to construct such an instrument, Mr. Weston, after much thought, turned to the application of the principle embodied in the electro-dynamometer—that is, a fixed coil acting on a movable coil ; but the mere selection of this principle by no means gave the solution of the problem. It must be evident that in order to be equally applicable to both continuous and alternating currents, the instrument must have practically no self-induction. How to obtain this condition with coils carrying alternating currents may be said to have been the problem solved by Mr. Weston. Starting with the fact that the self-induction of such a system depends primarily upon the strength of the current and the number of turns in the coils, Mr. Weston at once set himself the task of reducing the current required to operate the instrument to the smallest possible amount. The corollary to this was, to construct the instrument so that its moving parts should have the least possible weight, and that the friction should be reduced so as to make the instrument as sensitive as possible. To what degree Mr. Weston has succeeded in fulfilling these conditions will be apparent when we state that the moving coil, pointer, springs, and pivots of the new instrument weigh together only 31 grains, that is, less than one-fourteenth of an ounce.

The new instrument is made in two types with single and double scale. Fig. 1 represents the single-scale instrument.

The most essential part of the instrument, of course, is the system of fixed and movable coils, the latter being shown enlarged in Fig. 2. The movable coil consists of copper wire ·002in. in diameter. The diameter of the coil is 1¼in., and it is wound so that it presents a ¼in. square section, consisting of 525 turns. As the proximity of any considerable quantity of metal near the coils would introduce disturbing factors, it became necessary to avoid the use of a supporting spool for the wire of the movable coil, which, upon trial, was found to be quite stiff enough without a spool. The pivots upon which the coil turns are attached to it by means of small aluminum plates, which are first cemented to the coil and then wound with silk thread. The pivots consist of hardened steel, which are ground to gauge and polished. The entire movable system, as stated above, does not exceed 31 grains in weight.

It might be urged that the weight of the coil could have been still further reduced by the employment of aluminum wire ; and this, as a matter of course, also suggested itself to Mr. Weston. Indeed, his first instruments actually embodied aluminum wire coils, but it was found that aluminum could not be drawn practically below ·005 or ·006 of an inch, although Mr. Weston himself has, with great care, succeeded in drawing it down to ·00325 ; but as a still finer wire was needed in order to meet the requirements of the case, Mr. Weston was obliged to fall back upon copper, aluminum being employed wherever possible in the other parts of the movable system. It will be noted that the coil is balanced practically for all positions in the same manner as a watch balance, and, as in the magnet type of Mr. Weston's instruments, acts against the force of very delicate springs which also serve to carry the current to and from the coil.

It will also be noticed that the coil is provided at its lower end with a disc which constitutes part of the friction device provided for the purpose of damping the instrument. It will be evident that, as above stated, the placing of any metal near the coils to effect damping would cause injurious reactions. In the same manner magnetic damping was not permissible, as it would cause the indications to differ with the rate of frequency of the alternating current ; hence it became necessary to control the instrument by mechanical means in order to bring the parts quickly to rest. The brake in the instrument illustrated is combined with the contact-key shown as the hard rubber knob in Fig. 1. The brake normally presses against the disc and holds the moving parts rigid. When the key is depressed the current is first turned on, and then the friction is gradually reduced just sufficiently to allow the coil to gradually move along until, by the time the key is fully depressed, it has reached the position due to the action of the current and

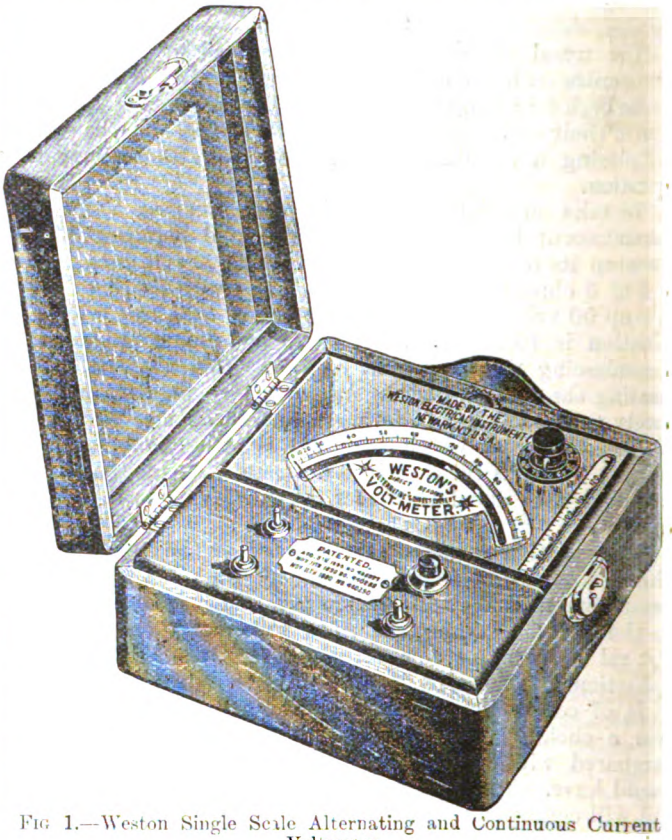

Fig. 1.—Weston Single Scale Alternating and Continuous Current Voltmeter.

indicates the proper reading on the scale. Thus while the instrument in itself is not dead-beat, the means provided by the brake allow readings to be taken nearly as quickly as with a dead-beat instrument.

The stationary coil which surrounds the movable one just described, consists of wire ·003 inch in diameter, the number of turns of which is as small as possible compatible with securing the necessary field of force, the coil being wound on a very thin hard rubber shell. The amount of current needed to move the index

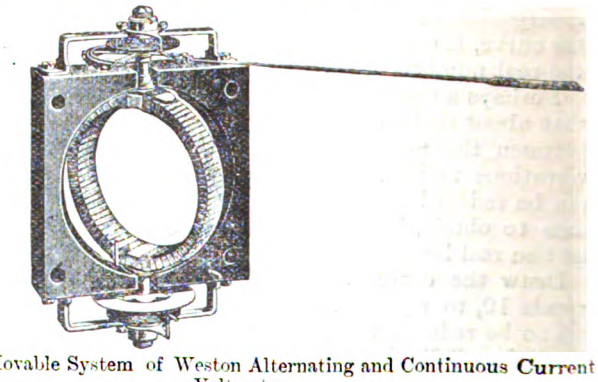

Fig. 2.—Movable System of Weston Alternating and Continuous Current Voltmeter.

across the entire scale differs somewhat in the various ranges made, varying from ·02 to ·056 of an ampere in the two-scale instrument, with the lower scale reading to 60 volts and the upper to 120. The resistance of the instruments averages for 60 volts about 1,100 ohms, and for 120 volts about 2,200 ohms. In single-scale instruments the resistance is generally much higher and the current lower. The principal resistance is in the form of a non-inductive resistance coil outside of the operative system, which is placed in series with the latter, the movable and fixed coils also being in series.

Not the least important part of the instrument is the means afforded by it of obtaining correct readings at all ranges of working temperature. It is a common practice of instrument makers to

Digitized by Google

attach to their instruments a table giving the temperature corrections, based merely on the changes in the resistance of the copper coils in the instruments; but it by no means follows, as will be presently shown, that such corrections will give accurate results, and, that, indeed, the indications may vary very largely from the truth when so corrected. While it is true that an increase in temperature of 5°F., for instance, increases the resistance of copper by about 1 per cent., a like change of temperature in the magnetic system of an instrument may cause changes which may be either positive or negative in their nature, according to the type of instrument. In Mr. Weston's magnetic voltmeters the relationship is such that the increased resistance due to increased temperature in the wire is almost exactly counterbalanced by an increase in the magnetic system, due to elevation of temperature. Consequently the instrument itself compensates almost perfectly for the change in resistance of its coil, due to changes in temperature. The new alternating-current instrument has decided the fact that it was impracticable to compensate directly for both of these sources of error; but there is added a thermometer, the bulb of which extends over and comes in contact with the coils, and is so flattened and contains such a small amount of mercury as to give quick response to the slight changes in temperature of the coil. The stem of the thermometer is placed below the glass cover, and can be easily read.

The compensation for changes in temperature is provided for by means of a minute rheostat shown at the right-hand corner of the instrument, which has a dial graduated into 20 parts, each indicating a change of 2½° F., and the whole extending between 60 and 100° F. This provides for a change in temperature of 50deg., which is sufficient for all practical purposes. To compenseate for temperature, therefore, it is only necessary to note the reading on the thermometer and to turn the pointer of the rheostat to the mark corresponding to the temperature indicated by the thermometer. The actual changes in the resistance due to temperature are small, as a large proportion of the resistance is German silver, less than one-tenth of it being copper.

A question which many will ask regarding the instrument is, Will the indications vary with currents of different number of alternations? The practical elimination of effects of self-induction as described above is the best answer to this question. Experiment has shown that no difference can be detected in the readings of this instrument between a perfectly continuous current and one varying from that up to 300 alternations per second, a range covering all practical systems of distribution in use at the present time, and proving the instrument to be practically without self-induction.

THE PROBABLE FUTURE OF CONDENSERS IN ELECTRIC LIGHTING.*

BY JAMES SWINBURNE.

It is always difficult to foretell the future in electrical engineering work, but it is sometimes interesting to try to see in what direction developments are likely to take place.

The first idea of the use of condensers was to employ them like storage batteries, and mention is frequently made by the early electric light patentees of their proposed use in this way. It is needless to remark that these inventors had not the most remote idea of the vast electrostatic capacities needed for storing by the hundred ampere hours.

The project of using condensers instead of transformers is by no means dead. It has been recently taken up on scientific principles by Mr. Doubrava. As soon as a condenser is charged and discharged rapidly enough its size becomes manageable, and Mr. Doubrava is therefore working out a system in which condensers take the place of converters. This development is in good hands, and need not be discussed further. One great difficulty is in charging condensers with direct currents. A condenser of the capacity of a farad charged with one volt contains, if the expression be allowed, only half a joule. If a condenser is charged by being connected to leads at one volt half a joule is wasted over resistance and the other half is stored. The only way of charging the condenser without loss is to connect it with an electromotive force which is gradually rising. Similarly, in discharging, the electromotive force must fall gradually. This condition is not at all difficult to attain.

The greatest development of the use of condensers will probably be in connection with alternating currents. It is doubtful whether ingenuity will ever design an arrangement of condensers that will take the place of transformers in practice. In one sense there is better material to work upon. A transformer is always inefficient on account of hysteresis. The loss by "soaking in" may be taken as analogous to the loss by hysteresis, but it is infinitely less in comparison. For instance, a condenser that takes 2,000 volts and 10 amperes has a loss which is too low to measure—that is to say, it is less than 5 or 10 watts. This loss is proportional to the size of the condenser, so that small sizes are just as efficient as large ones. In transformers this is not the case. A 100,000 watt transformer has a loss of from somewhat less than 1,000 up to about 5,000 watts according to the design, and if the 100,000 watts is made up of a number of small transformers the loss is much greater.

The uses for condensers are already developing. In the first place, they can be used to supply magnetising or exciting currents to all sorts of machinery, and also to apparatus that takes lagging currents. It must be remembered that the magnetising current in any receiving apparatus means a demagnetising current in the generator. As an example that will soon be common, and is also striking, we may take that of running arc lamps off 100-volt circuits with choking coils in series with them. As far as the lamp is concerned, there is no better arrangement than running it off a 100-volt circuit with a choking coil in series with it to reduce the terminal pressure to about 30 volts. If such a lamp takes 10 amperes, the apparent power taken is 1,000 watts, but the real power is probably less than 300 watts. The dynamos at the station have thus to supply large "idle" currents. These not only lead to armature heating, but also demand extra excitation. If many arc lamps are used, more dynamos become necessary, as no machines will stand three times their normal armature currents, even though they are out of step with the electromotive forces. Such currents, therefore, lessen the plant output, or, as as it is often loosely called, the "plant efficiency." To overcome this trouble, all that is necessary is to place condensers in shunt to the choking coils and lamps, or in shunt to the high-pressure leads. The last arrangement is best, as it admits of arranging the condensers at the central station. In addition to this, condensers for 2,000 or 1,000 volts are easier to make than those for 100 volts. Condensers for such low pressures cost too much in tinfoil, and are somewhat bulky, because the dielectric has to be made thick in proportion, to make certain of the absence of flaws. At present comparatively few arc lamps are run in this manner, but that is because nearly all the alternating-current systems now in use have small transformers in houses and high-pressure mains about the streets. This barbarous custom is rapidly going out of fashion. It has taken people a long time to realise that there is an appreciable waste of power in house transformers, and high efficiencies were always quoted, the losses in the copper alone being considered. The loss in the iron is more generally understood now, and the sub-station system is coming into use. This involves automatic gear, and, though certainly an improvement on the old methods, is hardly likely to live long. The system of avoiding loss by automatic gear is bound to go as soon as makers alter their designs and make their transformers more efficient at light loads. The feeder system will then prevail. A high-pressure feeder will then have a transformer at the other end feeding into a low-pressure network. The transformer will have so little loss that it will not be worth while to switch it out of circuit during the day. Even if automatic gear is used, it is not necessary to employ a complicated system of switches. An automatic switch in the secondary, which is controlled by the current in the primary, is all that is required. On breaking the primary circuit at the station, the switch opens the secondary. On making the primary, the secondary makes itself. Whichever method comes into use, it is probable that arc lights will be run off 100-volt circuits with choking coils, and condensers will be required at the stations. Of course, there is no reason why arc lights should not be run off high-pressure circuits by means of constant-current transformers. This system has never come into use in this country, probably because the low cost of this method is not generally appreciated.
